Resource Allocation

- Allocating indivisible goods among multiple agent is an important problem in AI.
- Drawbacks of centralized methods(combinatorial auction):
 - Elicitation process and winner determination procedure can be expensive.
 - Agents may be reluctant to reveal their full preferences.
 - In some real world situation, monetary side payments are impossible or unwelcome.
- [*Bouveret and Lang, IJCAI, 2011*] studied a sequential elicitation-free protocol.

- 4 Strategy Issues under ϖ_A
- 5 Conclusion

Our Method

Generalization the sequential protocol:

- A parallel policy (i.e., an agent selection policy) is given before allocation begins.
- At every stage, some agents are selected to report their favorite objects among remains.
- If an object is reported by more than one agent, then they draw lots to get it.

Definition

- m indivisible objects $\mathcal{O} = \{o_1, \dots, o_m\}$, and n agents $\mathcal{N} = \{1, 2, \dots, n\}$;
- \succ_i : agent i 's ordinal preference (strict total order) over \mathcal{O} ;
- *profile* R : $R = \langle \succ_1, \dots, \succ_n \rangle$;

 - Parallel Protocol
 - Comparison with Sequential Protocol
- 4 Strategy Issues under ϖ_A
- 5 Conclusion

Assumption

- Agents have additive utilities;
- Scoring function maps the rank to the utility value(same for all agents);
- Full independence (all profiles are equally probable).
- Two specific scoring functions:
 - Borda: $g_B(k) = m - k + 1$
 - lexicographic: $g_L(k) = 2^{m-k}$.

Social Welfare

- Social welfare: $sw_F(\pi) = F(u_1(\pi), \dots, u_n(\pi))$
 - $u_i(\pi)$: agent i 's expected utility over all profiles.
- Two specific social welfare functions:
 - utilitarian criterion $F_u(u_1, \dots, u_n) = \sum_{i=1}^n u_i$.
 - egalitarian criterion $F_e(u_1, \dots, u_n) = \min\{u_i | 1 \leq i \leq n\}$.

 - Definition
 - Assumption
- 3 Parallel Protocol and Policies**
 - **Parallel Protocol**
 - Comparison with Sequential Protocol
- 4 Strategy Issues under ϖ_A
- 5 Conclusion

Parallel Policy

- a parallel policy is a function ϖ :
 $(Reporting_set \times loser_set)^* \rightarrow Reporting_set$.
- Given a finite sequence $\sigma = \langle \mathcal{N}_1, \mathcal{N}'_1 \rangle, \dots, \langle \mathcal{N}_k, \mathcal{N}'_k \rangle$, ϖ designates the set of agents reporting at stage $k + 1$.
- An allocation history can be induced by ϖ , which is nondeterministic.

Two Parallel Policies

Two specific parallel policies:

- All-reporting policy: all the agents report at every stage.
- Loser-reporting policy: all the agents losing some lot at the current stage report at the next stage

Example

Let $m = 5$, $n = 3$, All-reporting policy. Suppose

$R = \langle \succ_1, \succ_2, \succ_3 \rangle$ s.t.

- $\succ_1 = o_1 \succ o_2 \succ o_3 \succ o_4 \succ o_5$,
- $\succ_2 = o_4 \succ o_2 \succ o_5 \succ o_1 \succ o_3$,
- $\succ_3 = o_1 \succ o_3 \succ o_5 \succ o_4 \succ o_2$.

stage	1	2	3	total
<i>agent1</i>	$\frac{1}{2}o_1$	$\frac{1}{2}o_2$	$\frac{1}{3}o_5$	$\frac{1}{2}o_1 + \frac{1}{2}o_2 + \frac{1}{3}o_5$
<i>agent2</i>	o_4	$\frac{1}{2}o_2$	$\frac{1}{3}o_5$	$o_4 + \frac{1}{2}o_2 + \frac{1}{3}o_5$
<i>agent3</i>	$\frac{1}{2}o_1$	o_3	$\frac{1}{3}o_5$	$\frac{1}{2}o_1 + o_3 + \frac{1}{3}o_5$

 - Parallel Protocol
 - Comparison with Sequential Protocol**
- 4 Strategy Issues under ϖ_A
- 5 Conclusion

Optimal sequence

- [*Bouveret and Lang, IJCAI, 2011*] conjectured that finding an optimal sequential policy is NP-hard.
- [*Kalinowski et al., IJCAI, 2013*] proved that the alternating policy (i.e., 1212...) is optimal for two agents under Borda scoring function (utilitarian criterion).
- However, the problem of finding optimal sequence for more than two agents, or under other scoring functions, is still open.
- In another hand, parallel policy ϖ_A (i.e., all-reporting) is very natural and simple.

Comparison

Table: Utilitarian Social Welfare of ϖ_{π^*} and ϖ_A under g_B

m	$n = 2$			$n = 3$			$n = 4$		
	π^*	SW_{π^*}	SW_A	π^*	SW_{π^*}	SW_A	π^*	SW_{π^*}	SW_A
4	<u>22</u>	12.292	12.292	<u>31</u>	13.083	13.297	<u>4</u>	13.583	13.885
5	<u>221</u>	18.625	18.625	<u>32</u>	20.033	20.382	<u>41</u>	20.800	21.351
6	<u>222</u>	26.396	26.396	<u>33</u>	28.622	28.840	<u>42</u>	29.600	30.377
7	<u>2221</u>	35.396	35.396	<u>331</u>	38.511	38.864			
8	<u>2222</u>	45.820	45.820	<u>332</u>	49.936	50.381			
9	<u>22221</u>	57.487	57.487						
10	<u>22222</u>	70.569	70.569						

- Conjecture 1: Under utilitarian criterion and convex scoring functions, $sw(\varpi_{\pi^*}) = sw(\varpi_A)$ when $n = 2$, and $sw(\varpi_{\pi^*}) < sw(\varpi_A)$ when $n > 2$.

Comparison(continued)

Table: Egalitarian Social Welfare of ϖ_{π^*} and ϖ_A under g_B

	$n = 2$			$n = 3$			$n = 4$		
m	π^*	SW_{π^*}	SW_A	π^*	SW_{π^*}	SW_A	π^*	SW_{π^*}	SW_A
4	<u>221</u>	6.000	6.146	<u>33</u>	3.750	4.432	<u>4</u>	2.500	3.471
5	<u>1222</u>	9.000	9.313	<u>332</u>	5.000	6.794	<u>44</u>	4.500	5.338
6	<u>2221</u>	13.125	13.198	<u>3321</u>	9.000	9.613	<u>443</u>	5.833	7.594
7	<u>12222</u>	17.333	17.698	<u>32133</u>	12.250	12.955			
8	<u>22212</u>	22.725	22.910	<u>11332232</u>	15.000	16.794			
9	<u>122222</u>	28.429	28.744						
10	<u>2212221</u>	35.200	35.285						

- Conjecture 2: Under egalitarian criterion and convex scoring functions, $sw(\varpi_{\pi^*}) < sw(\varpi_A)$ for any number of n and m .

Strategy Issues under All-reporting Policy

- All-reporting policy is not *strategyproof*.
- Assumptions:
 - Manipulator is pessimistic(risk averse);
 - All agents but the only one manipulator act truthfully;
 - Manipulator knows all other agents' preferences.
- A manipulation problem M (for agent 1) consists of $\langle \succ_2, \dots, \succ_n \rangle$, and a target set of objects $S \subseteq \mathcal{O}$.

Strategy Issues(continued)

- A *manipulation problem* can be addressed in polynomial time.
- Problem of finding an optimal strategy under lexicographic scoring function can be solved in polynomial time.
- We conjecture that under the Borda scoring function, the problem of finding an optimal strategy is NP-hard.

Conclusion

- We proposed a parallel elicitation-free protocol for allocating indivisible goods.
- All-reporting policy outperforms the optimal sequential policies in our test cases.
- We addressed some strategy issues when manipulator is pessimistic.

Future Work

- Proof of the conjectures about the social welfare induced by All-reporting policy.
- Manipulation when the manipulator is risk neutral or risk seeking.
- Other parallel policies that can outperform All-reporting policy in some social welfare criteria.
- Elicitation-free protocol for allocating sharable goods.
