Dynamic Mechanisms

- Dynamic mechanisms for resource allocation:
 - price adjustment processes;
 - market-clearing prices;
 - Walrasian equilibrium.
- Main issue of a dynamic mechanism:
 - Can a procedure lead to an equilibrium state?

Price Rigidities

- “Good” allocation= Economy efficiency + Social equality + computation tractable.
- Price rigidities may play a key role, for example:
 - Capped-price housing;
 - Limit price of stock;
 - Minimum wage.

Main Contributions

- Computational problems of dynamic auction proposed by [Talman and Yang, 2008]
- Proof about the existence of constrained Walrasian equilibrium
- Strategical issues based on “expected profits” and “expected prices”

- 5 Conclusion

Assumptions

- Valuation functions and prices are all integers.
- Buyers can afford the maximum price of any item.
- Every item has a lower bound price \underline{p}_a and a upper bound price \bar{p}_a .
- All buyers report their favorite items(making them get most profits) at every stage.
- Every buyer could only get one item.

Constrained Walrasian Equilibrium

Criteria of *constrained Walrasian equilibrium* $\langle \mathbf{p}, R, \pi \rangle$:

- $\mathbf{p} \in P$, R is a rationing system
- π is an equilibrium allocation
- If an item is not allocated to any buyer, price of the item should be lower bounder price.
- If $R(i, a) = 0$, then price of item a should be the upper bound price, and there is some buyer has it.
- If $R(i, a) = 0$, we change value of $R(i, a)$ to 1, then buyer i will demand item a .

Example

- $R(1, c) = R(3, c) = 0$
- Lower bound price $\underline{\mathbf{p}} = (0, 5, 4, 1, 5)$, Upper bound price $\bar{\mathbf{p}} = (0, 6, 6, 4, 7)$,
- Price vector $\mathbf{p} = (0, 5, 4, 4, 7)$,
- Allocation π : $\pi(1) = o$, $\pi(2) = c$, $\pi(3) = b$, $\pi(4) = a$, and $\pi(5) = d$.

$\langle \mathbf{p}, R, \pi \rangle$ is a constrained Walrasian equilibrium.

Table: Values, Profits, and Constrained Demand

buyer i	$u_i(o)$	$u_i(a)$	$u_i(b)$	$u_i(c)$	$u_i(d)$	$V_i(\mathbf{p}, R)$	$D_i(\mathbf{p}, R)$
1	0	4	3	5	7	0	{o,d}
2	0	7	6	8	3	4	{c}
3	0	5	5	8	7	1	{b}
4	0	9	4	3	2	4	{a}
5	0	6	2	4	10	3	{d}

Over-demanded Set

- A set X' is *over-demanded*, if $|\{i \in N \mid D_i \subseteq X'\}| > |X'|$.
- X' is *minimal* if no strict subset of X' is over-demanded.

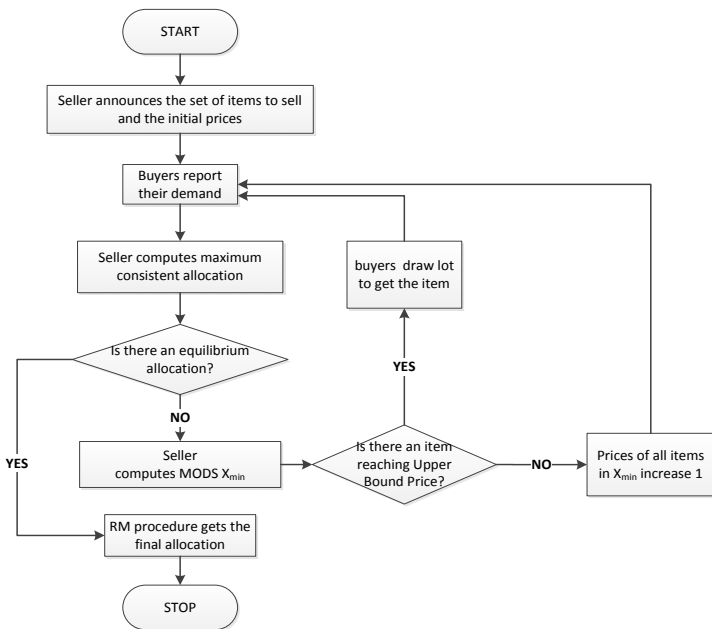

Theorem 1

There exists an over-demanded set of items in $\mathcal{D} = (D_i)_{i \in N}$ if and only if there does not exist an equilibrium allocation.

- We proposed an algorithm called MODS to find a minimal over-demanded set.

Properties of MAPR

- MAPR always terminates and is polynomial in $|N|$, $|X|$, and $\sum_{a \in X} (\bar{\mathbf{p}}_a - \underline{\mathbf{p}}_a)$.
- MAPR leads to a constrained Walrasian equilibrium.

Strategy Issues

- Since the history of MAPR is nondeterministic, we defined buyers' *expected profits* and items' *expected prices*.
- MAPR is generally not *strategyproof* (in the sense of expected profits).
- Two interesting questions:
 - 1 Is MAPR strategyproof for some restricted domains?
 - 2 When it is not, how hard is it for a buyer who knows the valuations of the others to compute an optimal strategy?

Strategy Issues(continued)

- When there are two buyers, MAPR is strategyproof.
- We conjecture that the manipulation problem of MAPR is NP-hard.

Conclusion

- There exists an over-demanded set if and only if there is no equilibrium allocation.
- We proposed an algorithm to compute the Over-demanded set.
- We proposed an algorithm MAPR which can find a constrained Walrasian Equilibrium in polynomial time.
- We proved that when there are two agents, MAPR is strategyproof.

Future Work

- Complexity of manipulation by one buyer.
- Problem of manipulation by two or more buyers.
- Collusion problem: manipulating prices between some buyers and the seller.
- Problem of allocating divisible goods and sharable goods under price rigidities.
