**BARAM DELTA & NORTH SABAH  
EOR CENTRE**

# **SPWLA**

## **Measurements, analysis and interpretation of SCAL data**

# Outline

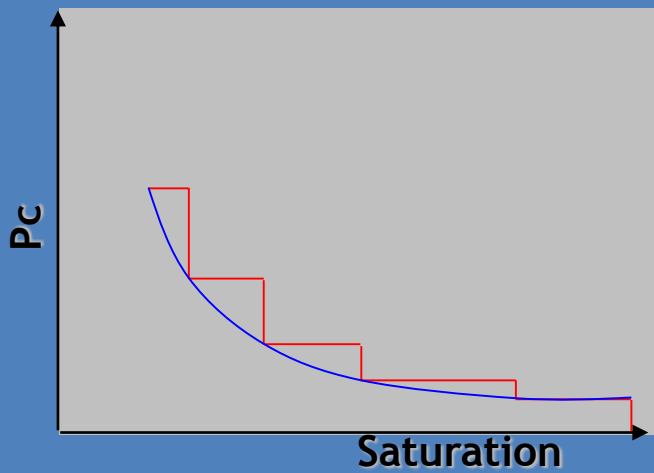

---

- Experimental Design
- Drainage versus imbibition
- Experimental Pc techniques (with and without resistivity)
  - Mercury Injection technique
  - Equilibrium technique
  - Continuous injection technique
  - Centrifugation
- Numerical interpretation
- Examples of misleading SCAL results
- Examples of correct/incorrect use of reliable SCAL data in models

# Experimental Design

# Experimental Design

# Experimental Design

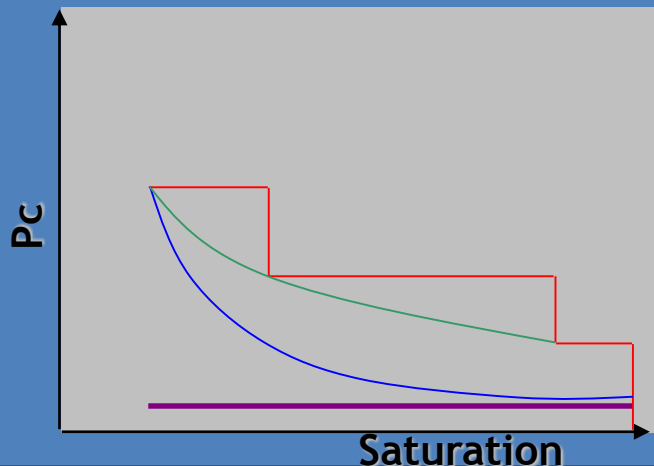

# Experimental Design

Which Pc curve is the correct one ?

If all capillaries was 100 % oil wet (prior to invasion), how does the Pc look like

# Experimental Design

This core plug was used in a SCAL study !

Reservoir Laboratories AS      A      Company: PDO

# Experimental Design

Lenormand's phase-diagram for primary drainage:

$$Nc = \frac{q \cdot \mu}{\Sigma \cdot \sigma} \quad M = \frac{\mu_{invading}}{\mu_{defending}}$$

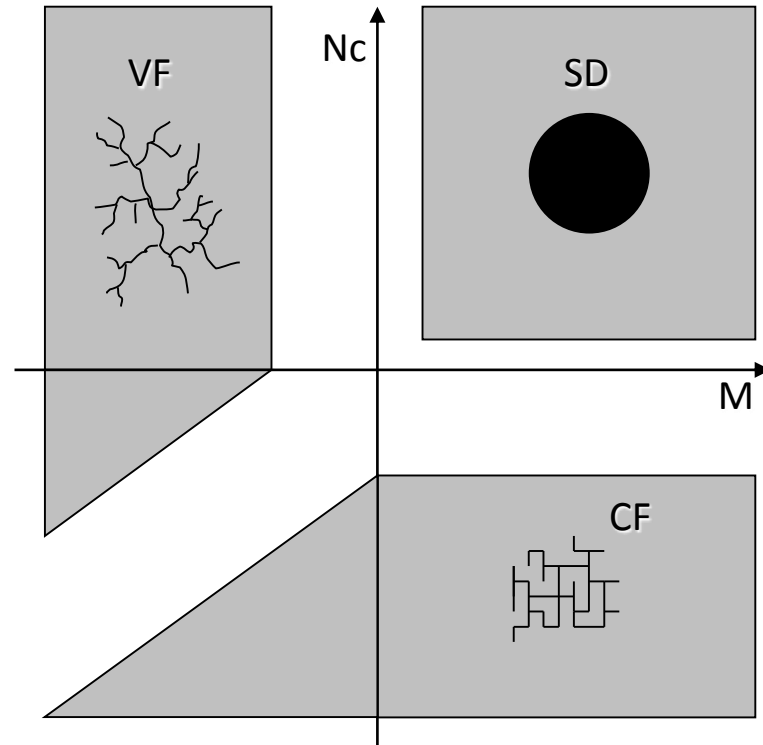

Where:

$q$  Injection rate

$\sigma$  Interfacial tension

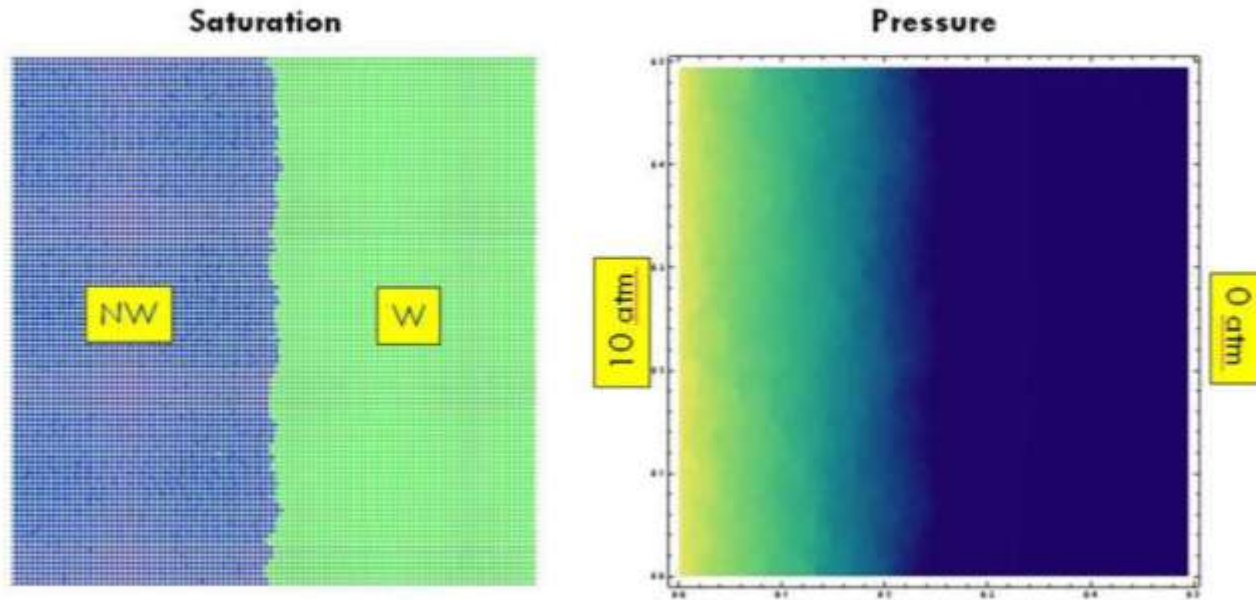

$\Sigma$  Cross section of inflow

$\mu$  Viscosity

# Experimental Design

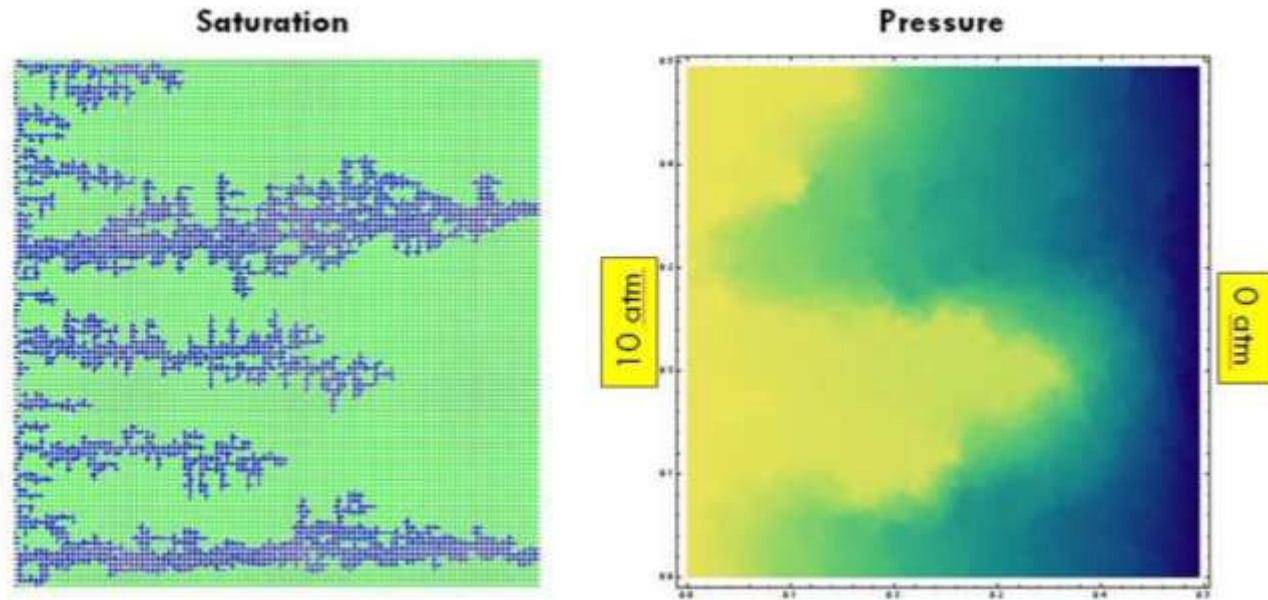

## Stable Displacement:

Viscous force (from the invading phase) controls the flood  
Pressure drop-Mainly from inlet injection side till front

$$N_c = \frac{q \cdot \mu}{\Sigma \cdot \sigma} \quad M = \frac{\mu_{invading}}{\mu_{defending}}$$

# Experimental Design

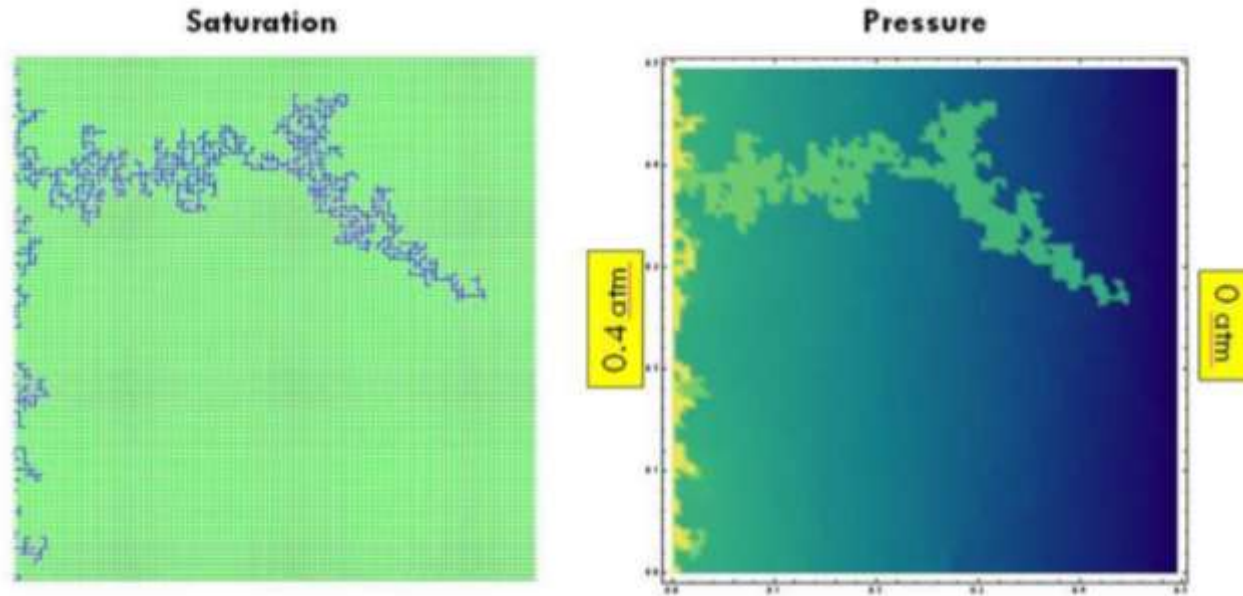

## Viscous Fingering:

Viscous force (from the defending phase) controls the flood  
Pressure Drop—mainly from finger tip till the outlet end

$$N_c = \frac{q \cdot \mu}{\Sigma \cdot \sigma} \quad M = \frac{\mu_{invading}}{\mu_{defending}}$$

# Experimental Design

## Capillary Fingering:

Capillary forces controls the flood

Pressure drop - In principle constant across the continuous fluid interface

$$N_c = \frac{q \cdot \mu}{\Sigma \cdot \sigma} \quad M = \frac{\mu_{invading}}{\mu_{defending}}$$

# Drainage versus imbibition

---

Drainage

- Must be done in initially water wet preference

# Drainage versus imbibition

Water wet

Oil wet

## Wettability:

- Affects all multiphase property behavior such as relative permeability, capillary pressure, n-exponent

# Drainage versus imbibition

Primary Drainage 4

Increased capillary pressure  
Water connected in smaller pores

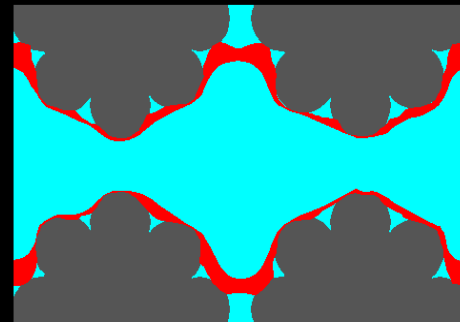

Imbibition, Water-wet 3

Oil is disconnected,  
low  $k_{rw}$

Imbibition, Mixed Wet 5

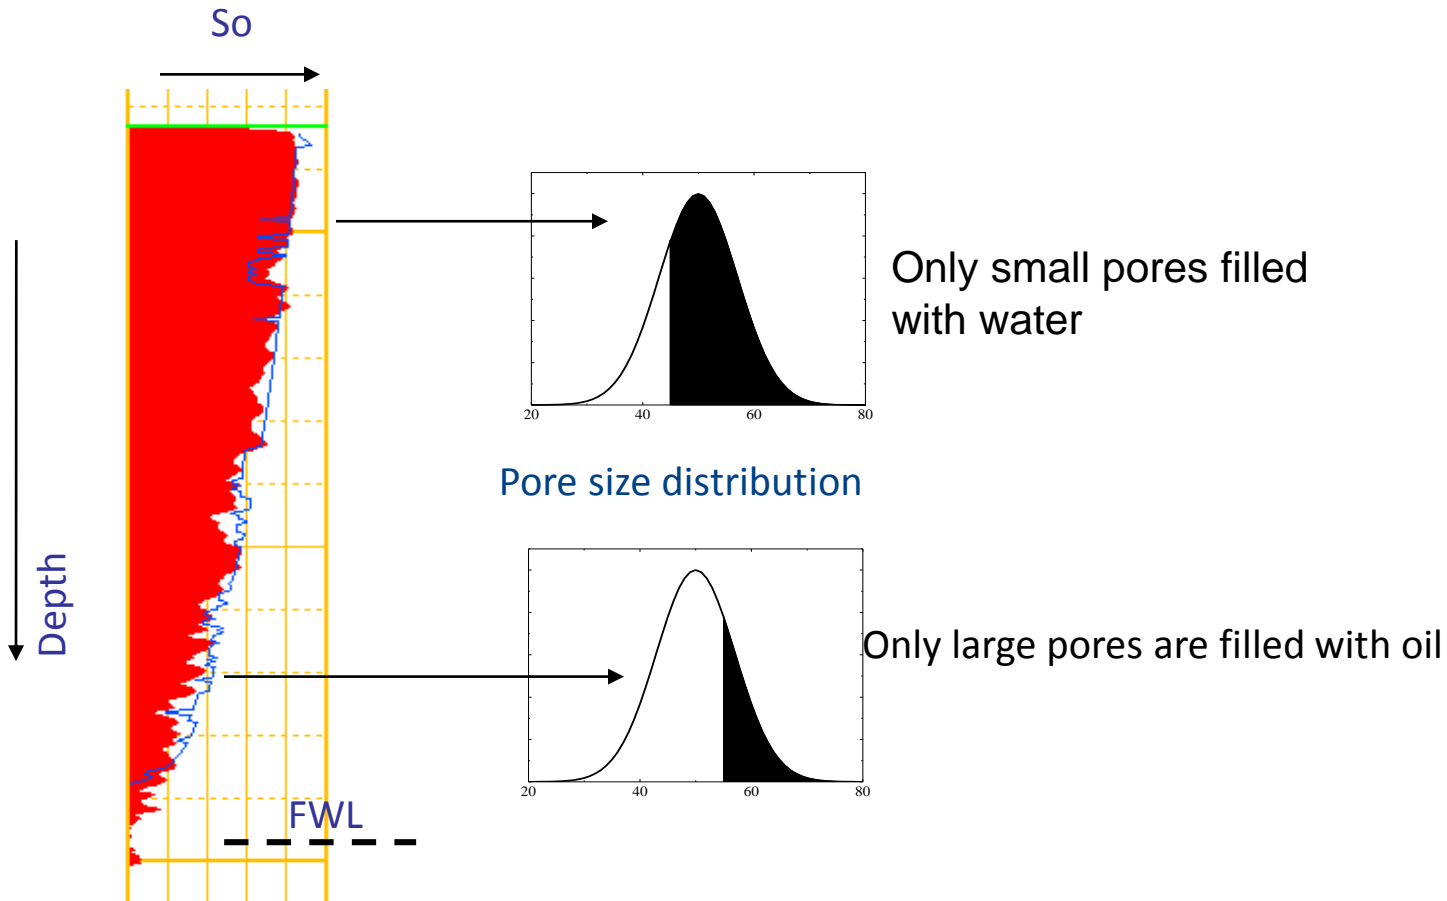

Oil drains from connected films  
high  $k_{rw}$

# Impact of wettability

## Wettability may not be a constant:

Non invaded capillaries that have never seen oil is water wet (by default)!

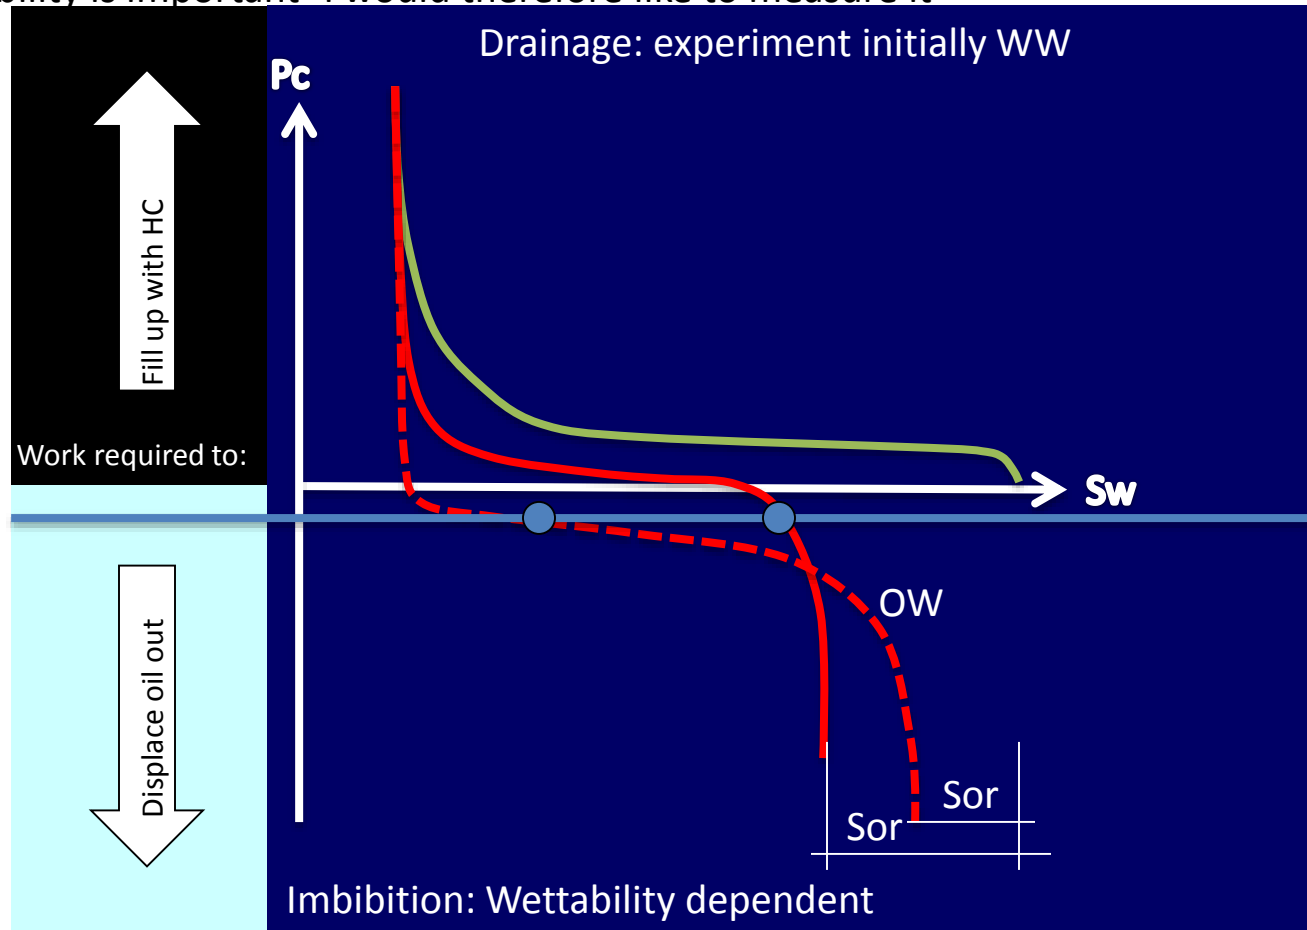

# Impact of wettability

## Common questions to SCAL experts:

- Field recovery factors is low, so why is  $S_{orw}$  from  $P_c$  experiment low ?
- Wettability is important- I would therefore like to measure it

$P_c$  curves are used in dynamic models-while Wettability Index is not

# Mercury Injection

Concept:

# Mercury Injection

Concept:

# Mercury Injection

Concept:

You are measuring conductance in the tube and pressure in the oil bath

# Mercury Injection

---

## Strength:

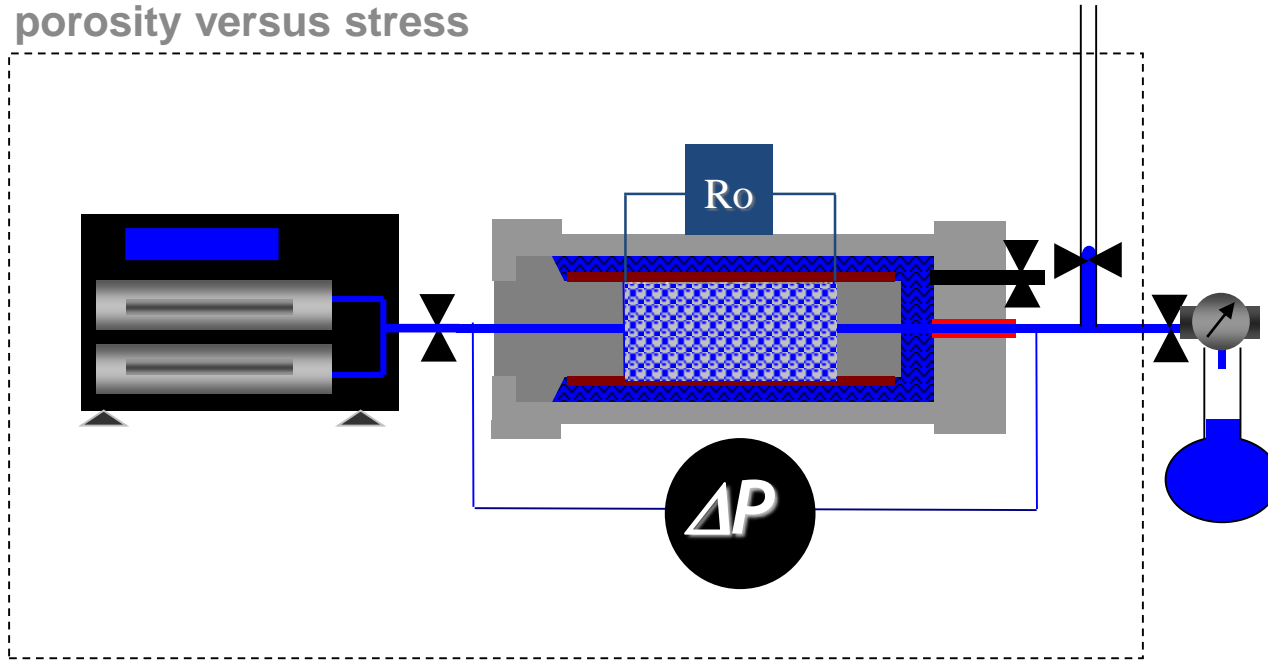

- Very fast technique (around 8 MICP curves per day/ machine)
- Give you simultaneously pore size distribution
- A reliable and accurate technique if proper procedure are established
- Cost

## Weakness

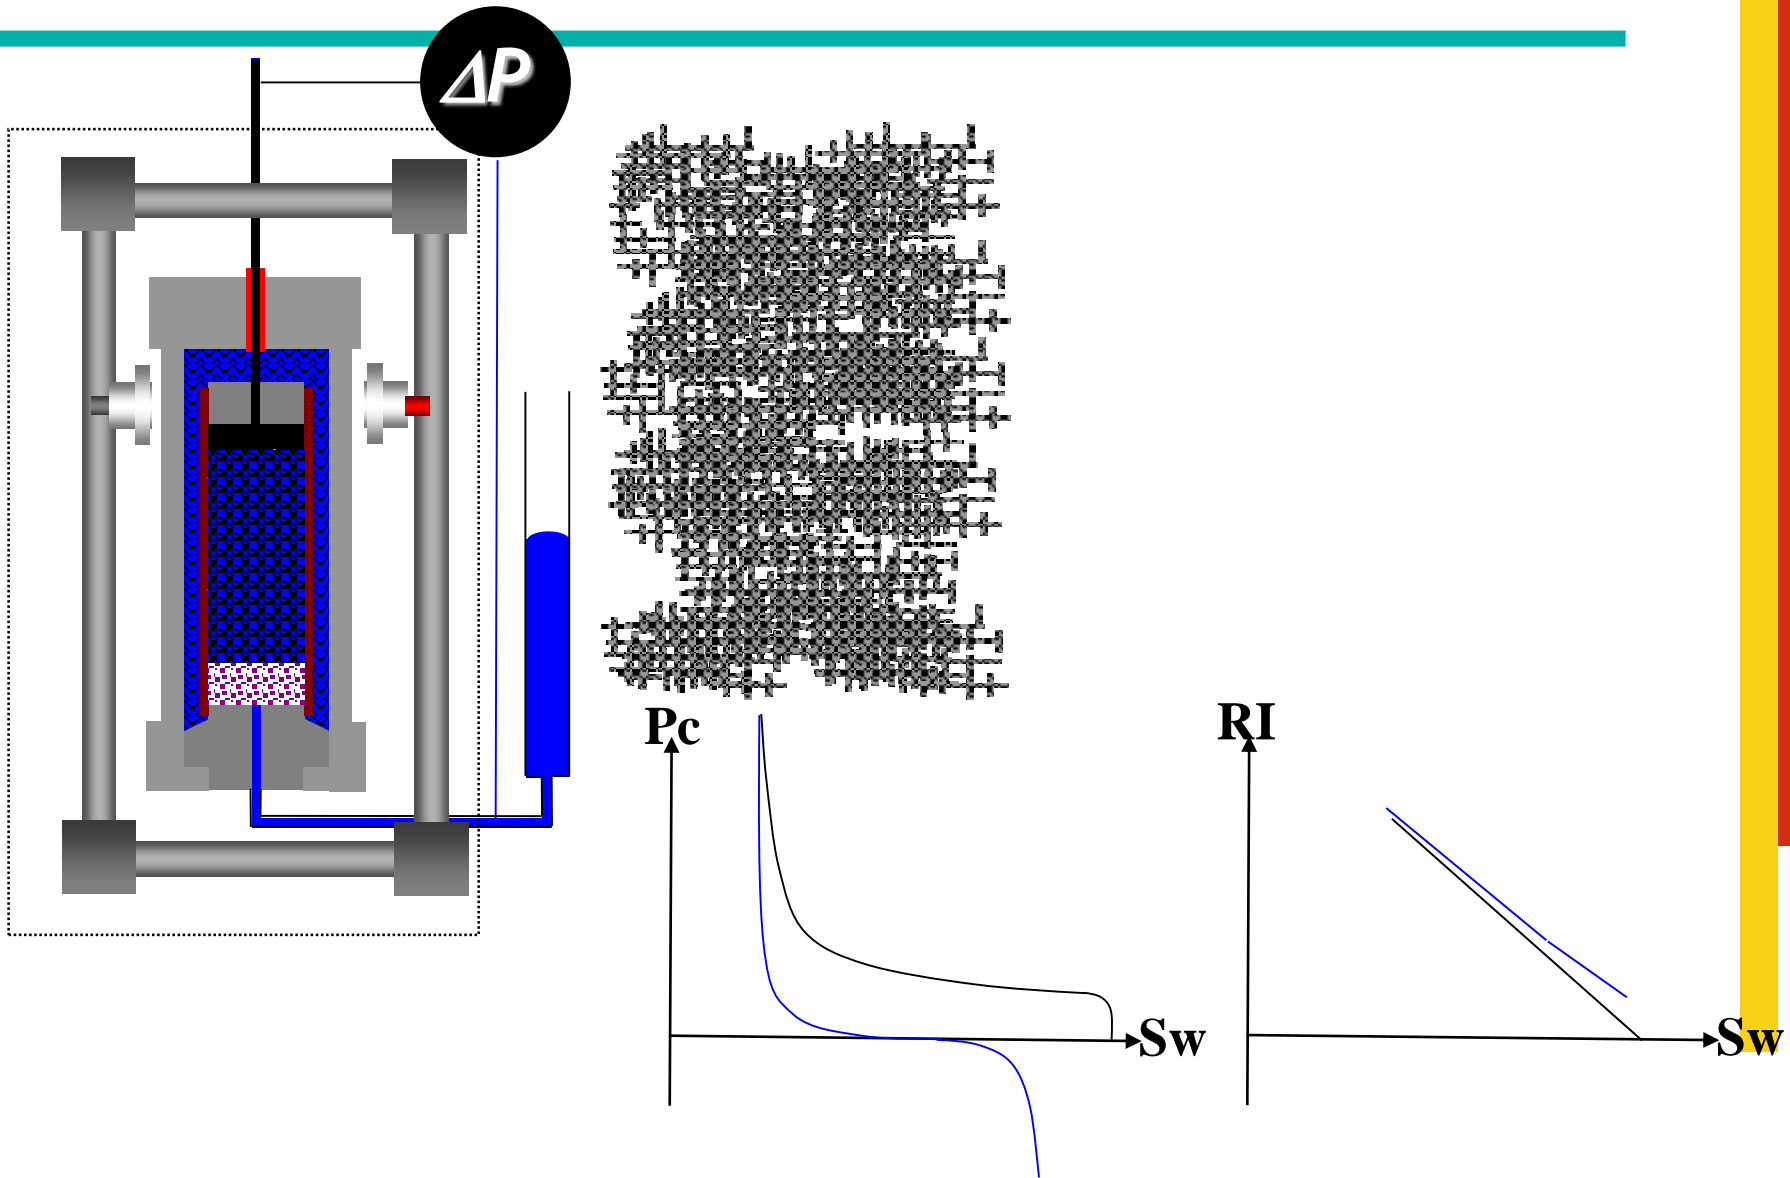

- Sample size (limited to a 1 inch core plug with 1 inch length)
- Its NOT a 2-phase experiment ( $S_{wc}=0$  @ 60 000 psi)
- Needs correction (conformance, clay bound water, stress)
- Questionable for vuggy material
- HSE aspect
- Questionable for friable or unconsolidated material
- Can not be combined with electrical properties (n exponent)

# Basic Properties

Kw, FRF and porosity versus stress

# Equilibrium technique (Porous Plate technique)

# Equilibrium technique (Porous Plate technique)

---

## **Strength:**

- It's a direct technique
- It does not require a model for converting measurements to  $S_w$  or  $P_c$
- It yield simultaneously resistivity behavior without changing set-up or conditions.
- It can be used at all types of conditions
- It is slow ( from a wettability restoration point of view)

## **Weakness**

- It is slow (from a interpretation point of view)
- In some cases difficult to combine with individual 4 electrode configurations

# Continuous Injection method

# Continuous Injection method

---

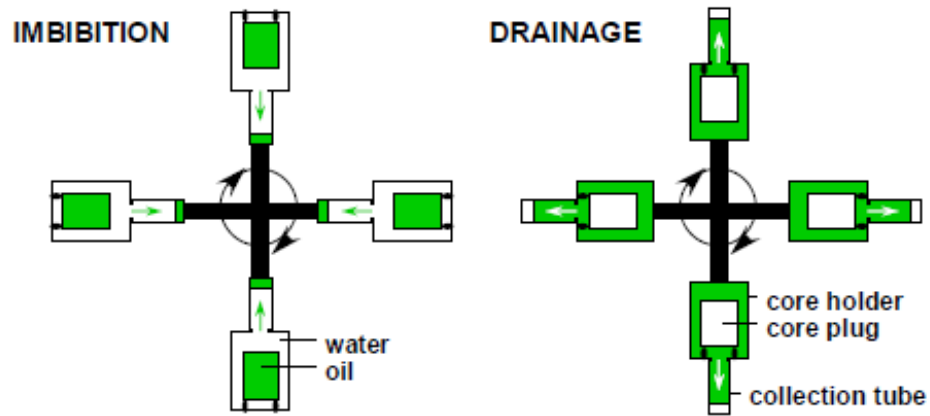

## **Strength:**

- Accurate technique if applied correctly
- It gives fast input parameters for the PP evaluation
- Can be used for all types of conditions
- It does not require a model for  $P_c$  and  $S_w$
- Method should always be followed by constant displacement pressure period (constant  $P_c$ )

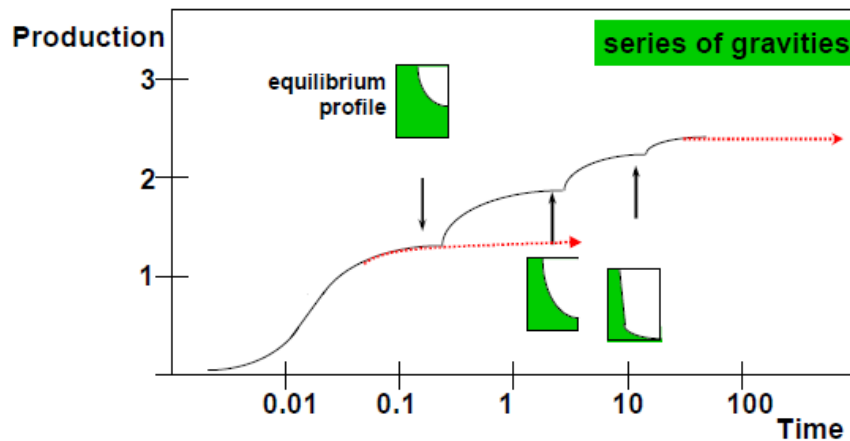

## **Weakness**

- Pseudo  $P_c$  is NOT an actual  $P_c$  curve
- Require correct rate design (Capillary number and Viscosity Ratio). Can be done by pre-simulations
- The technique have limitations for high viscosity oils and low permeability.
- Design of rates might require pre-simulations

# Centrifugation

$$Nb = \frac{\Delta\rho g K}{\sigma}$$

# Centrifugation

Average water saturation:

$$Sw(average) = 1 - \frac{V_{produced}}{V_{Pore}}$$

Capillary pressure on the inlet side

$$Pc(inlet) = \Delta\rho \cdot g \cdot L(cm) \cdot 0.01$$

$$g = (2\pi \cdot \omega / 60)^2 \cdot R_m \cdot 0.01$$

Hassler-Brunner: Assumption is constant capillary pressure gradient

$$Pc(HB)_n = \frac{(Pc_{inlet})_n + (Pc_{inlet})_{n-1}}{2}$$

$$Sw(inlet)_n = \frac{\partial Sw_{average} \cdot Pc_{inlet}}{\partial Pc_{inlet}} = \frac{(Sw_{average} \cdot Pc_{inlet})_n - (Sw_{average} \cdot Pc_{inlet})_{n-1}}{(Pc_{inlet})_n - (Pc_{inlet})_{n-1}}$$

# Centrifugation

---

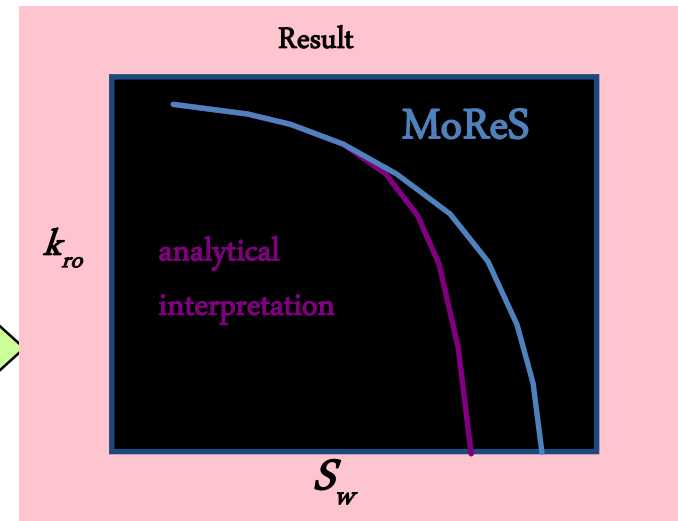

## Strength:

- It is a fast technique
- Can be done with stress.
- Reliable and accurate technique if speed designed is done correctly

## Weakness

- It requires a model for converting speed to  $P_c$ , and volumetric production to  $S_w$  (inlet end saturation)
- $P_c$  from lab needs to be corrected before use (by numerical interpretation)
- The technique is questionable for friable and unconsolidated material
- Cannot be combined with electrical properties (n exponent)
- Method have limitations in test temperature

# Numerical interpretation of experiments

- **MoReS simulations:**
- Capillary pressure
- Mobility both oil & water
- Experimental constraints

# Numerical interpretation of experiments

Saturation Profile

## Example 1: Misleading lab experiments- plug selection

OLD CT technology

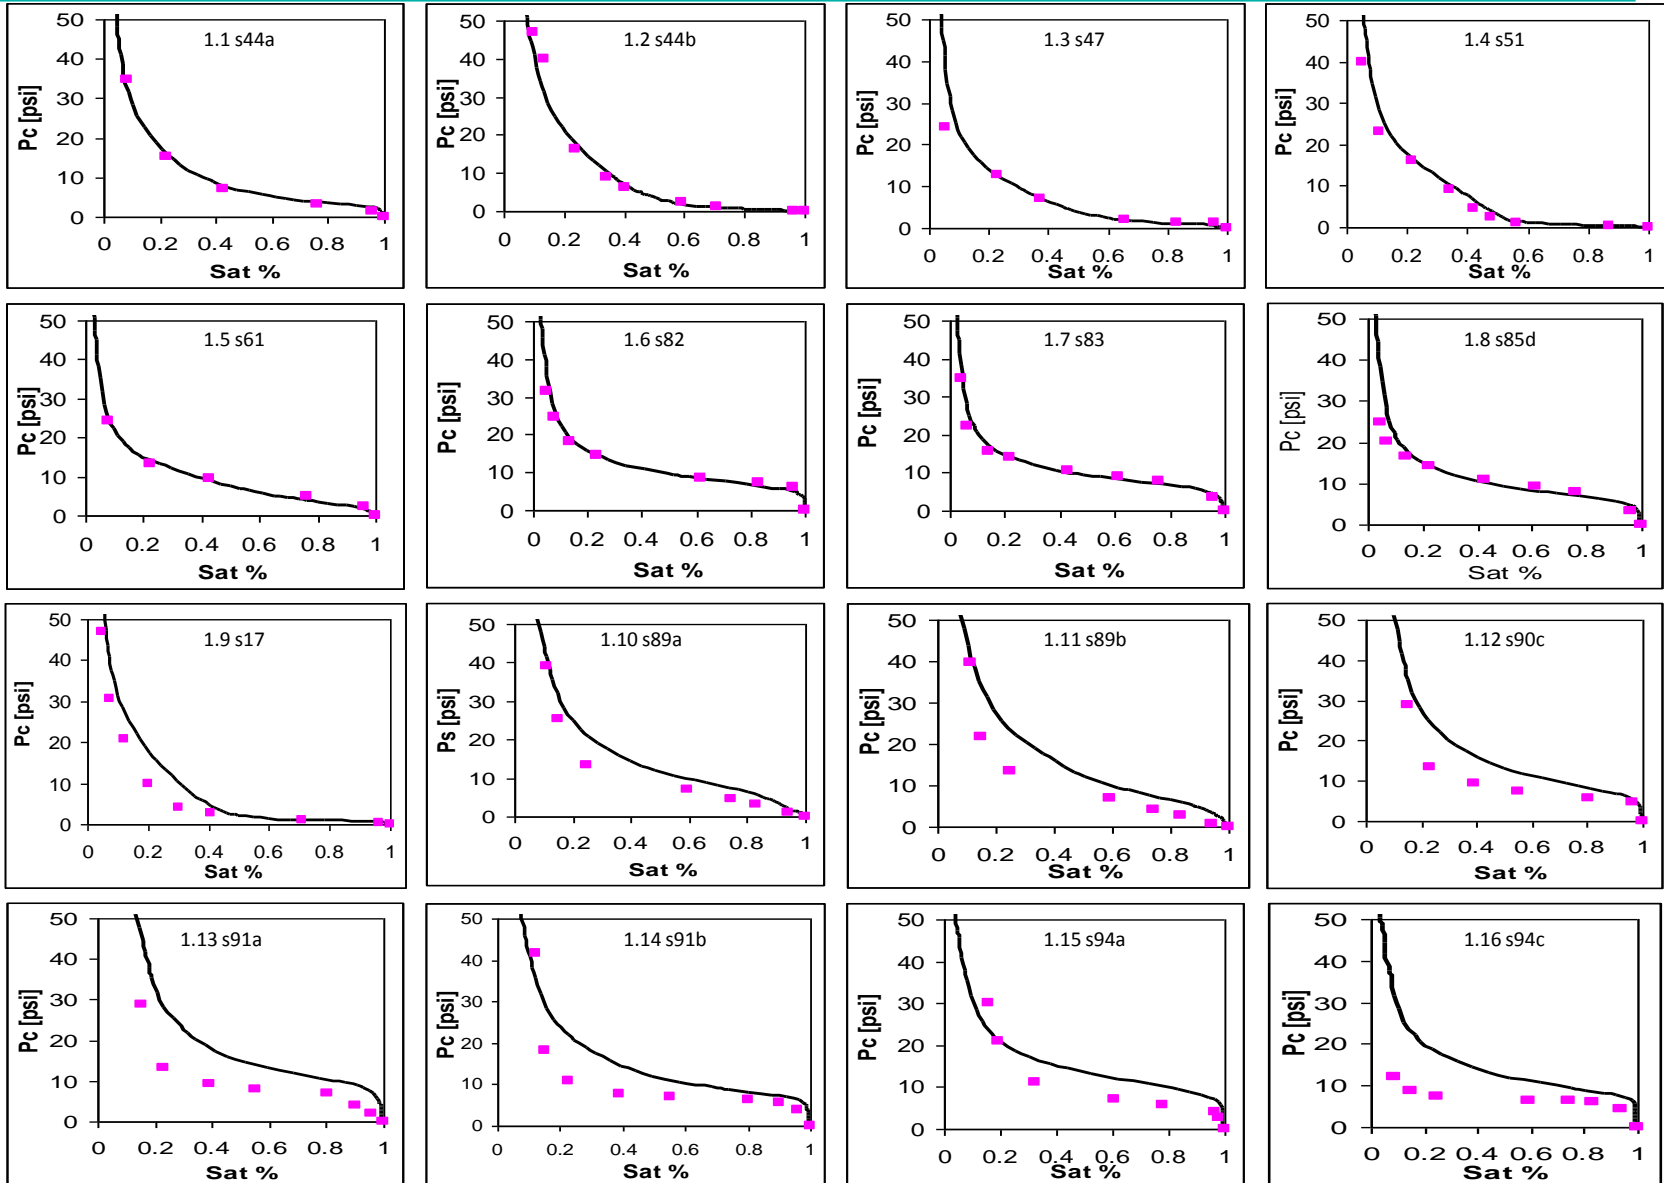

Helical CT technology

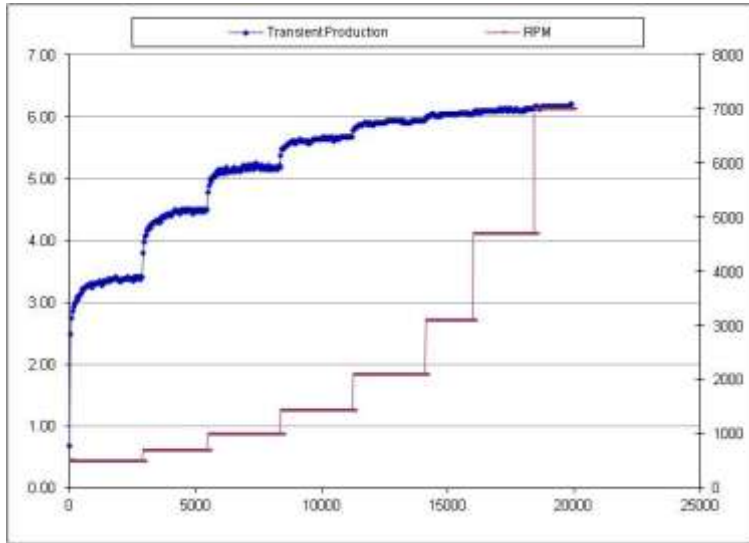

Assessment from LAB: Core Plug is suitable for SCAL

## Example 2: Misleading lab experiments – Pc experiments

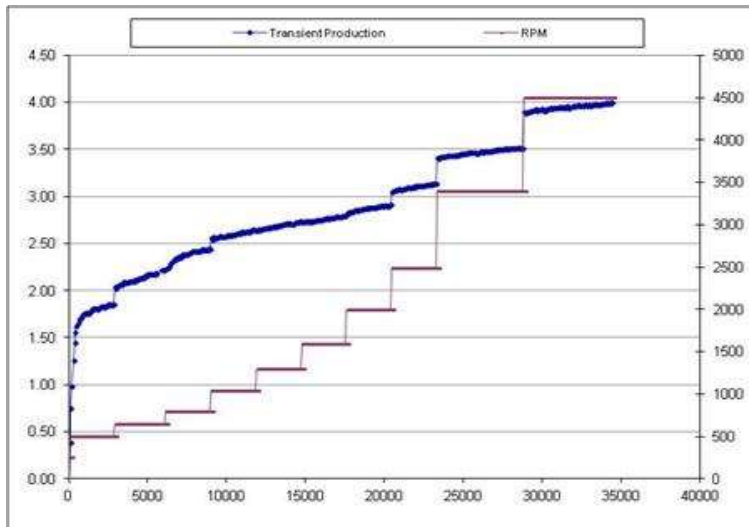

# Example 3: Misleading lab experiments -Centrifugation

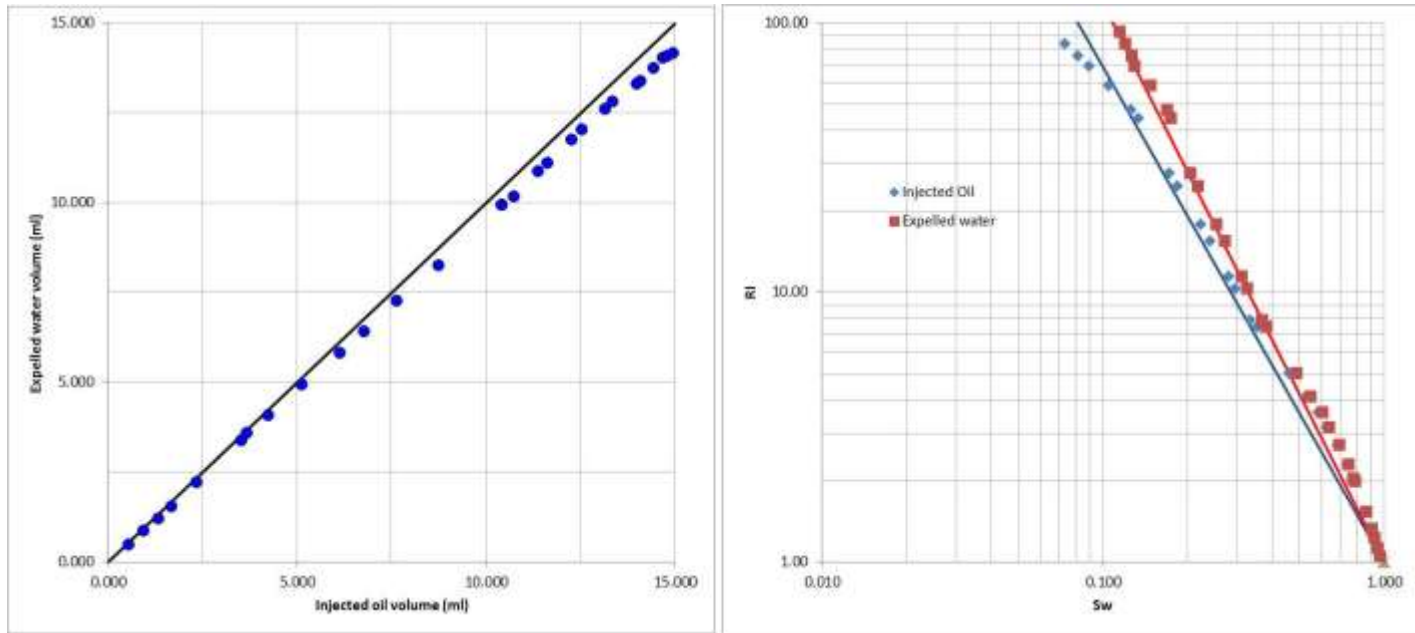

Good quality

poor quality

## Example 4: Misleading lab experiments- CI

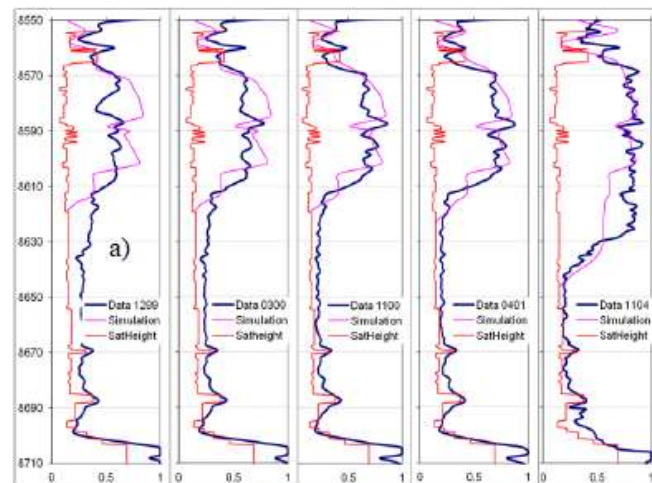

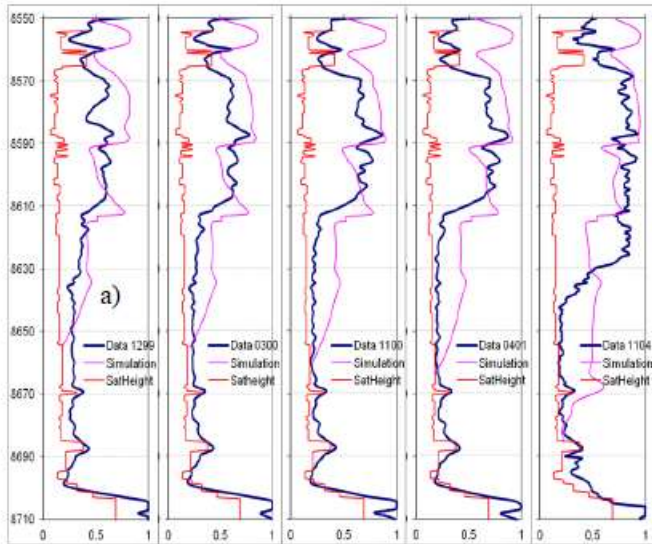

N-exp based on injected oil volume: 1.84 (reported by lab)

N-exp based on expelled water volume: 2.07

Lab's procedure does not take into account oil compressibility

# Example 1: Modelling with and without Pc IMB

Implemented in dynamic:  
Pc(DR)+Kr(IMB)

Implemented in dynamic model:  
Pc(DR and IMB) + Kr(DR and IMB) with  
Scanning curves

# Example 2: Modelled with and without scanning curves

Consistent  $P_c$  and  $K_r$   
With scanning curves

### Example 3: DR versus IMB n-exp in terms of understanding ROS
