

# Challenges with managing Linear Distortion in remotely sensed data Two Case Studies

Michael Olsen  
8/17/2023

OREGON GNSS USERS GROUP  
SERVING SURVEY & GIS PROFESSIONALS

# DISCLAIMER

*I have financial interests in the company EzDataMD LLC, and commercialization of technology involving point cloud data processing (e.g., EZProj). The conduct, outcomes, or reporting of this research could benefit EzDataMD LLC and could potentially benefit me.*

# Challenges

- Varying support of coordinate systems in 3D laser scan software (Earth is flat?)
- Many people are not aware\do not consider map projection distortion between grid and ground measurements
- Difficult and confusing to implement scale factors
- Distortion can be cm-level across small sites (<100m), leading to unreliable deformation analysis.
- Precision of software/las files can lead to truncation
- Issues scale with data size

Oregon State University  
College of Engineering

Schematic illustrating linear distortion, courtesy of Michael Dennis and Mark Armstrong, NGS

# Pixy dust (noun)

- Data collected through “SfM” or “phodar” techniques by someone with limited experience or minimal training either due to ignorance or just plain laziness. The operator/ provider are generally solely interested in how cheap and fast the data collection is. Use with **EXTREME CAUTION!**

# Case Study 1: Dotted the Coast

Strategies and considerations when using lidar data for coastal studies

# Coordinate System Options

Oregon State University  
College of Engineering

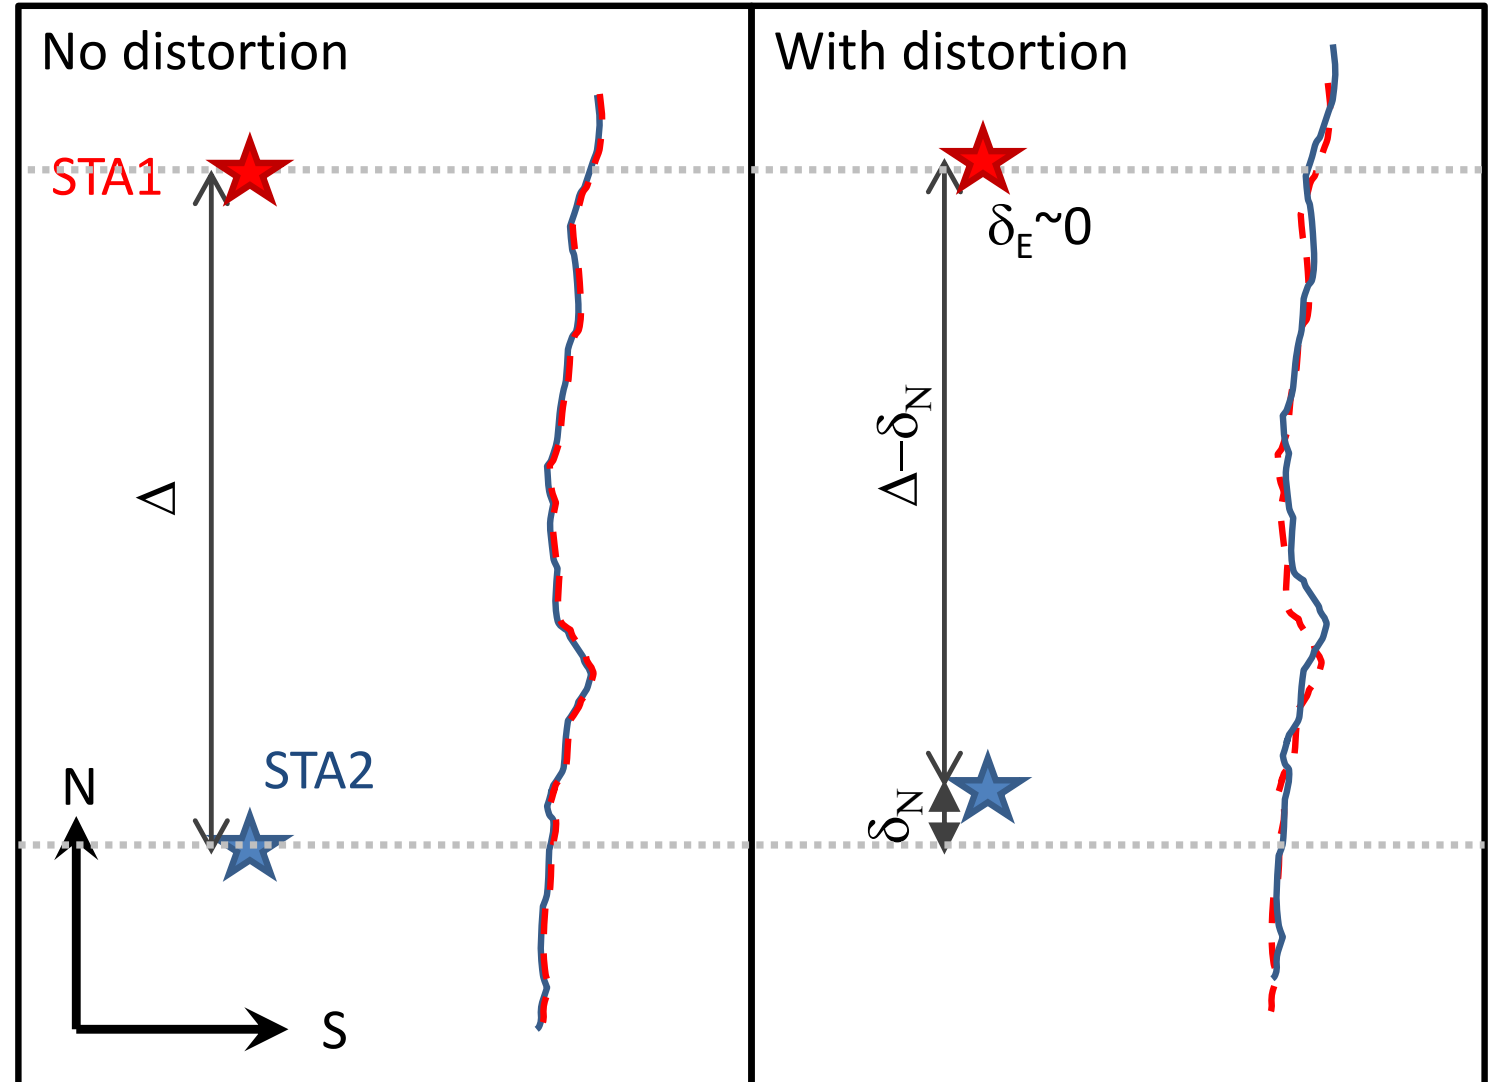

Coordinate System	Attributes		
	Design distortion	Advantages	Disadvantages
UTM	1:1,000	<ul style="list-style-type: none"> <li>- Commonly used for scientific studies</li> <li>- Much available data have been processed in UTM</li> <li>- Covers relatively large areas</li> </ul>	<ul style="list-style-type: none"> <li>- Large distortion</li> <li>- A regional scale study may straddle multiple zones (e.g., Zones 10 &amp; 11 for the US West Coast).</li> </ul>
State Plane	1:10,000	Commonly used for engineering and land surveying	- 2 distinct zones in state of Oregon, others for other states.
OCRS	1:100,000	- Low distortion	- Multiple small zones
ECEF	No distortion	<ul style="list-style-type: none"> <li>- Same coordinate system worldwide</li> <li>- true 3D coordinates</li> </ul>	<ul style="list-style-type: none"> <li>- Requires advanced geodetic computations to compute distances along the ground surface of the Earth</li> <li>- Large coordinates</li> <li>- Elevation, Z-up?</li> </ul>

# Theory

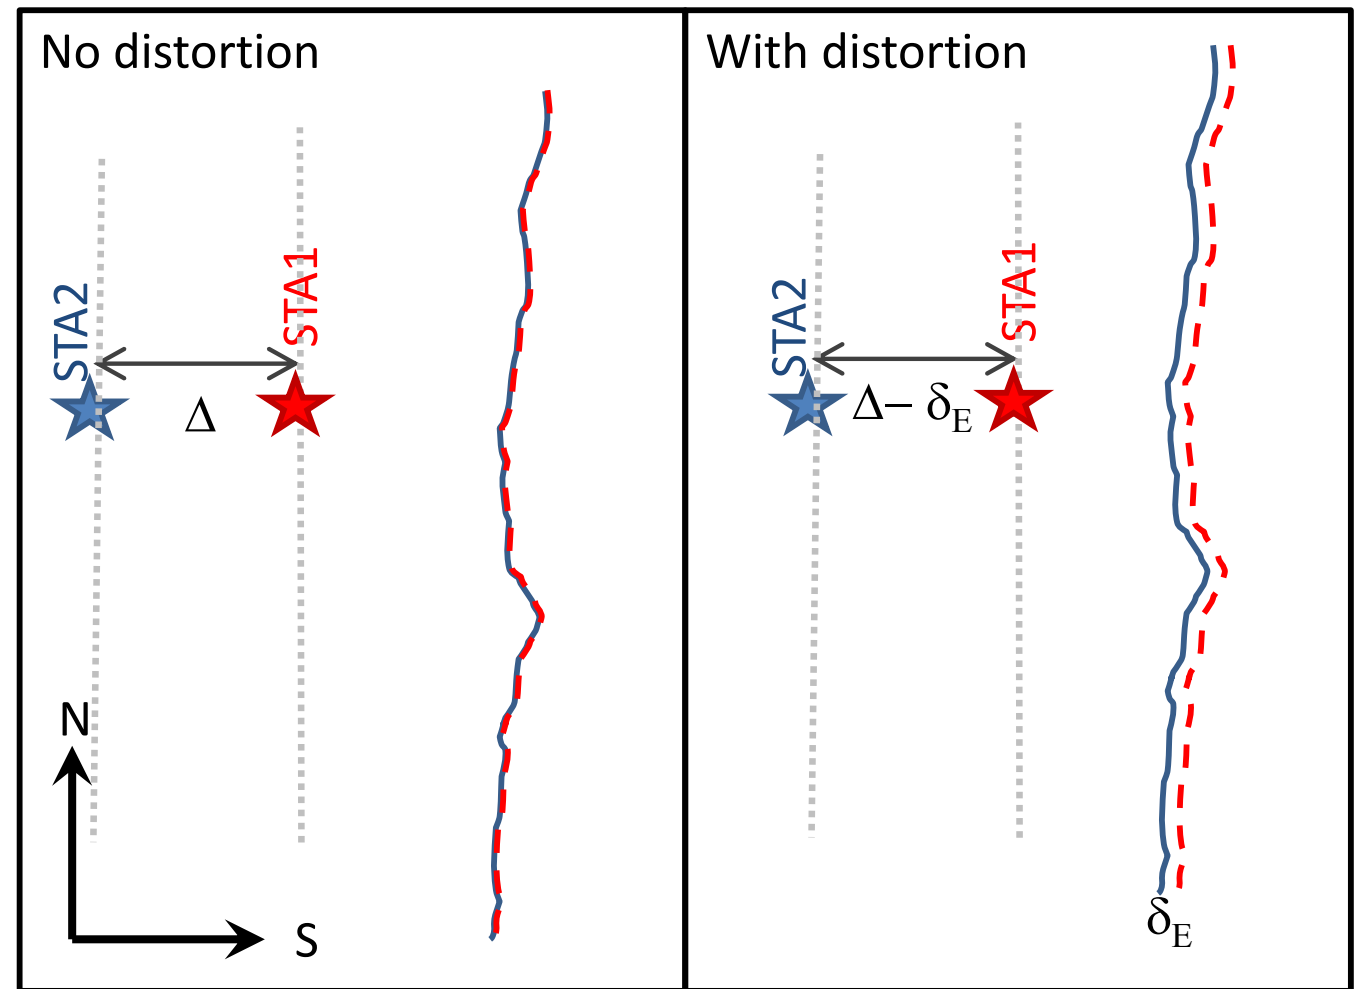

- Linear distortion effects are minimized when a systematic process is utilized and the topography is not very complex.

Note that the actual location (in the East direction) of the cliff on the grid will be equally incorrect in both of the scans. Typically scans will be spaced at a similar distance to their distance from the cliff, so this offset would be approximately  $\delta$ .

# Theory

- Linear distortion can be a significant problem if scans are done at varying distances from the cliff

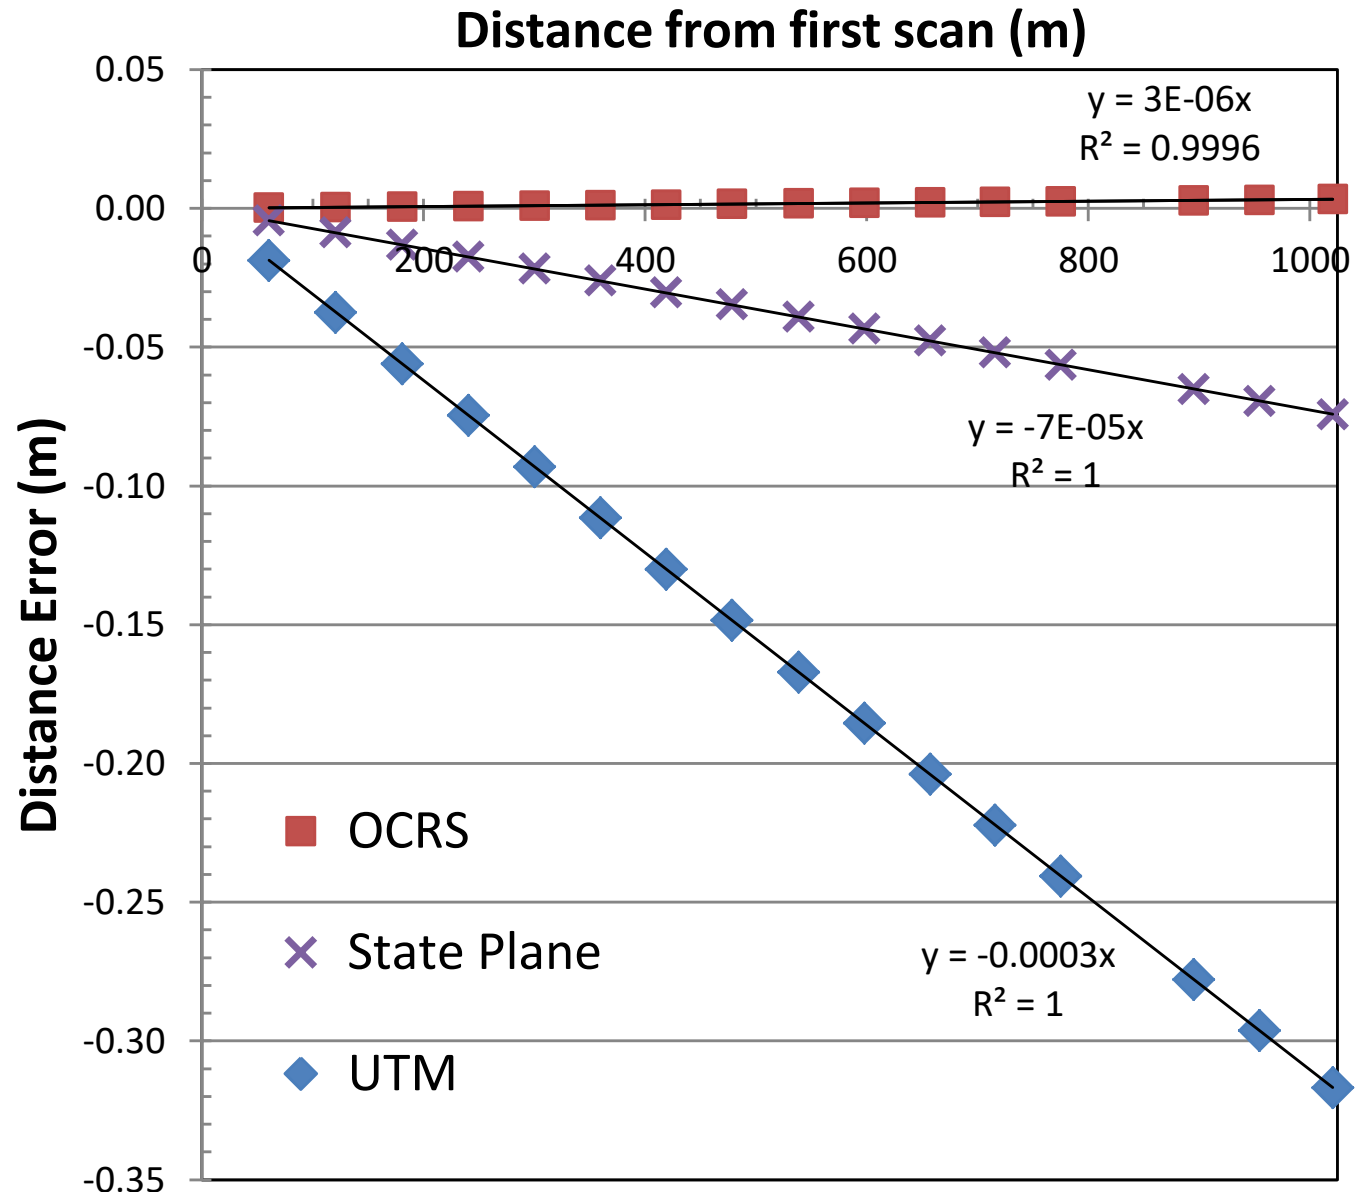

In this case, the actual location (in the East direction) of the cliff on the grid will not be equally incorrect in both of the scans. The offset of the cliff position that would appear as change would be approximately equal to  $\delta$ , because of the larger distance to the cliff in STA2 compared to STA 1.

$$RSTA2 = RSTA1 + D$$

$$RSTA2 = RSTA1 + D + dE$$

# Distance Distortion

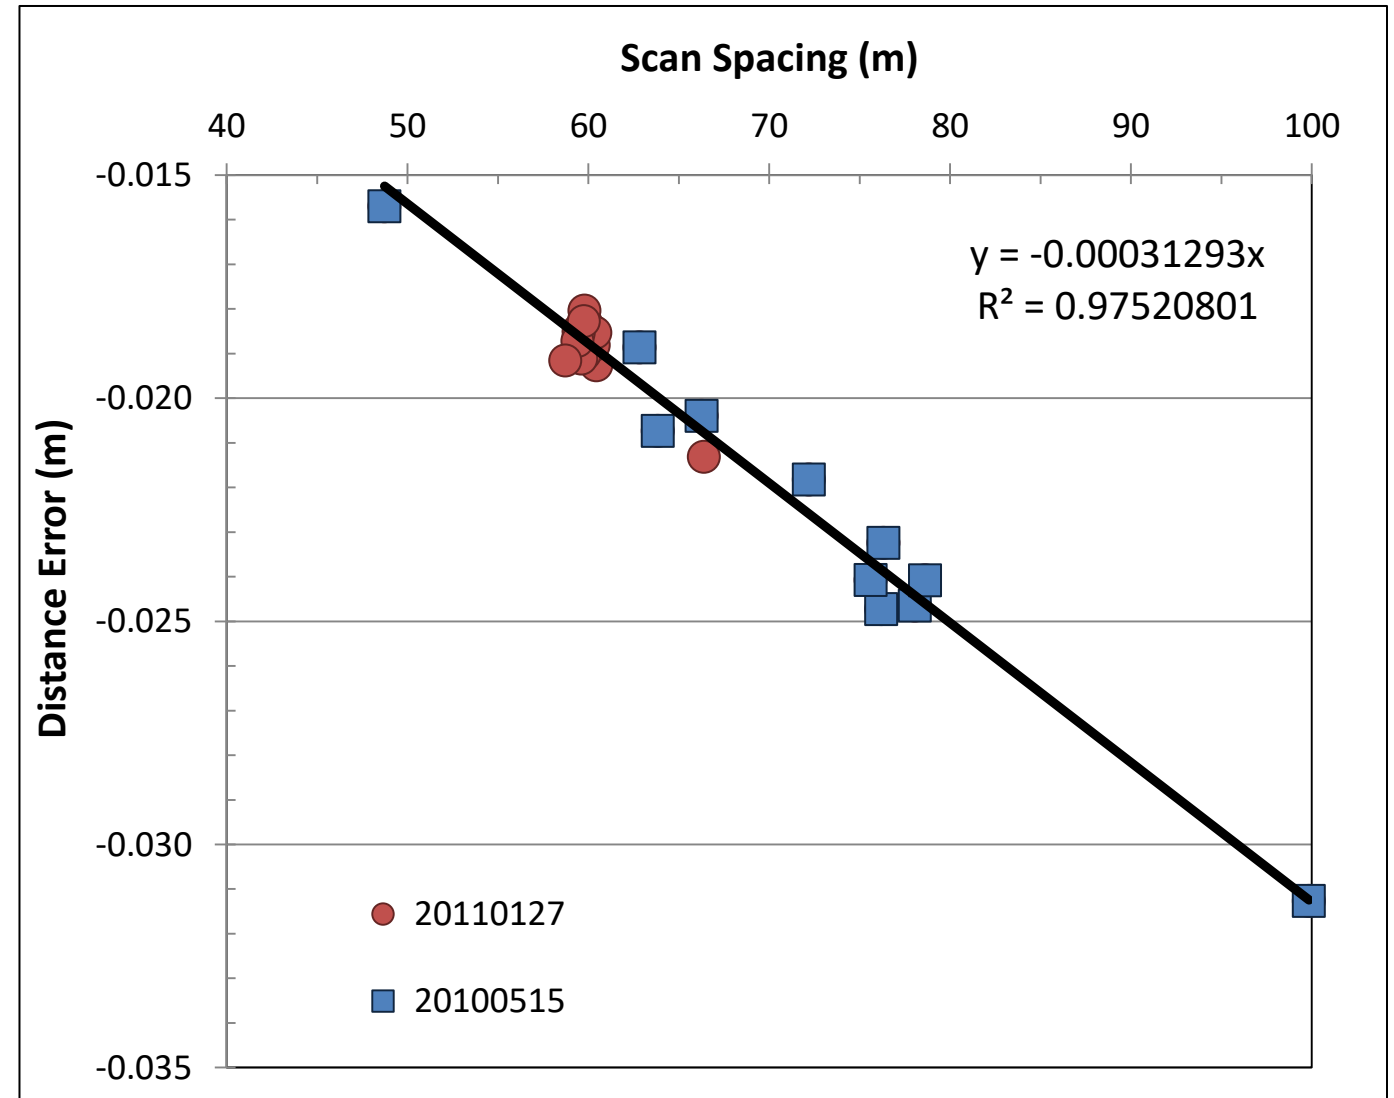

- Compare OCRS, State Plane, and UTM to ECEF 3D coordinates (between scans at end)
- UTM shows significant distortion, OCRS shows minimal distortion
- Distortion error is linear and systematic
- Scale factor (grid to ground)  
= 1- line slope

# Distance Differences

- UTM vs OCRS
- Automatic bias in data.
- Some gets “absorbed” in other registration parameters (e.g., rotation), mixed up in ICP.

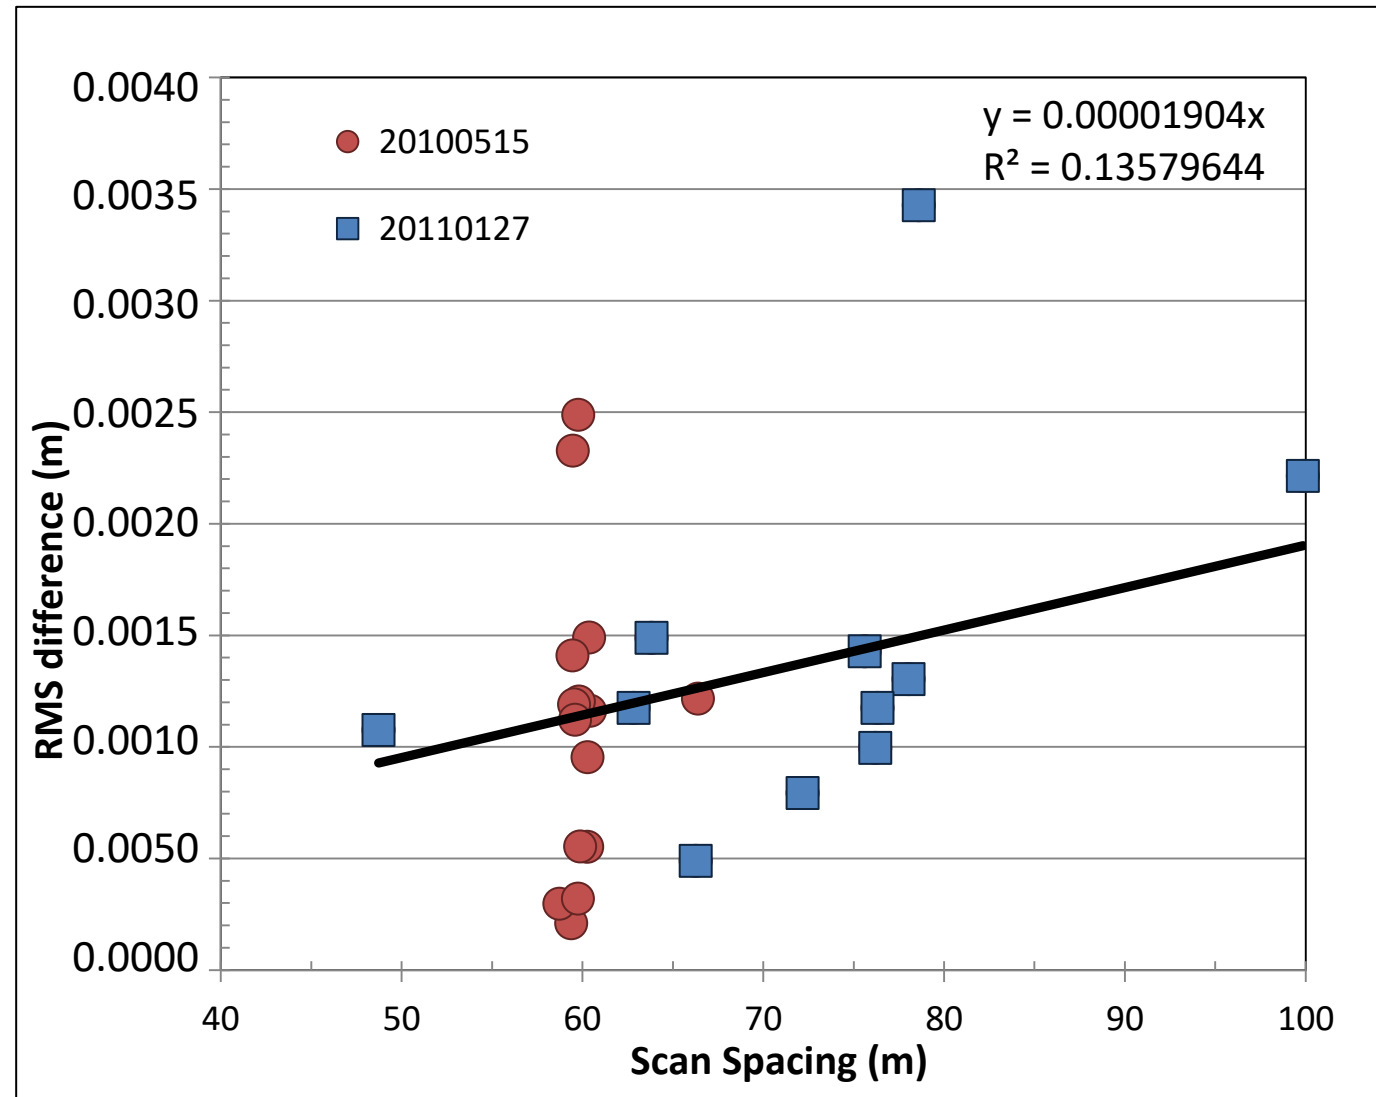

# Impact on adjacent scan matching

Oregon State University  
College of Engineering

- Compare RMS residual results using UTM and OCRS horizontal coordinates for scan positions
- Slightly higher RMS for UTM
- No clear relationship-likely due to RMS calculation method in scan data, estimating matching points (iterative closest point\plane)

# What to do?

- Limited support in lidar software for coordinate systems, projections directly
- Work in ECEF (Not intuitive)
- Use a LDP (e.g., OCRS)
- Scale measurements directly – as done with total station (need your own code). Apply SF to data before volume calcs. (Hard to be systematic/document what was done)
- Apply SF correction to volume and other calculations at very end!

# #1 Summary

- The low distortion projection (O CRS) minimizes error and shows consistent results to the fully 3D ITRF coordinates
- Effects on retreat rates\landslide advance can be substantial when scans are performed at different distances from the cliff
- Effects on volume calculations are small when a similar distance from cliff is maintained.
- Effects on scan alignment residuals are slight
- A systematic collection, processing and analysis process reduces the impact of distortion
- Several methods to account for distortion are presented

# North?

- Each coordinate system has a different north
- Tiling schemes vary

## Legend

# Why process at the point cloud vs raster level?

Oregon State University  
College of Engineering

- Closer to the source.
- Less accumulated error for transforms.
- Can control grid structure- no awkward intervals/spacing from unit conversions/transforms.
- Better representation of values for the cell as it is recomputed specifically for the grid structure. Reduces alignment/offset issues or interpolation.
- Can evaluate offsets\issues easier with the point cloud.

# What tools are available to transform?

Oregon State University  
College of Engineering

- ArcGIS (ESRI)
  - LP360 (GeoCue, uses ArcGIS)
  - LasTools (RapidLasso)
  - Vdatum (NGS)
  - EZProj
  - TLS software
    - Riegl Riscan Pro
    - Maptek Point Studio
    - Cyclone Reg360 (a few options)
  - SfM software
    - Context Capture
    - Agisoft Metashape
- Variable options
  - Slow
  - Datum realizations?
  - Coordinates varied by a few cm to dm.
  - Let's not start talking about epochs!!!
  - Batch processing???

Where available and uncertainties are established, VDatum supports the conversions among following:

- **Coordinate Systems:** Geographic, UTM, State Plane Coordinates (SPC), and geocentric (ECEF)
- **Horizontal Datums:** NAD27, NAD83\_2011, NAD83\_1986, NAD83\_FBN, and NAD83\_HARN; and ellipsoidal datums such as of ITRF, WGS84, and NAD83 serializations
- **Vertical Datums:**
  - **Ellipsoidal Datums:** NAD83\_2011, WGS84, ITRF88, ITRF89, ITRF90, NEOS 90, PNEOS 90, ITRF91, ITRF92, SIO/MIT 92, ITRF93, ITRF94, ITRF96, ITRF97, IGS97, ITRF2000, IGS00, IGS05, ITRF2005, IGS05, ITRF2008, IGS08, ITRF2014, IGS14, WGS84(transit), WGS84(G730), WGS84(G873), WGS84(G1150), WGS84(G1674), NAD83(PACP00), NAD83(MARP00)
  - **Orthometric Datums:** NAVD88, NGVD29, PRVD02, VIVD09, ASVD02, GUV04, NMVD03, HAWAII EGM2008, EGM1996, and EGM1984
  - **Tidal Datums:** MLLW, MLW, LMSL, DTL, MTL, MHW, LWD, MHHW and Local Tidal(LT)
  - IGLD85, LWD IGLD 1985, OHWM IGLD 1985
- **GEOID models:** [GEOID18](#), GEOID12B, GEOID12A, GEOID09, GEOID06 (Alaska only), GEOID03, GEOID99, and GEOID96
- **EGM models:** EGM2008, EGM1996, and EGM1984
- **xGEOID models:** xGEOID16b (BETA), xGEOID17b (BETA), xGEOID18b (BETA), [xGEOID19b\(BETA\)](#), and [xGEOID20b\(BETA\)](#)
- **Supported file format:** text(ASCII), LiDAR(.LAS, \*.LAZ) version 1.0, 1.1, 1.2 and 1.4 with Classification, ESRI ASCII Raster(.ASC), ESRI 3D shapefile

# The NAD 83(CORS 96) and NAD 83(NSRS2007) realizations of the North American Datum of 1983

Oregon State University  
College of Engineering

- NGS has adopted a realization of NAD 83 called NAD 83(NSRS2007) based on a realization of coordinates at ~70,000 passive geodetic control monuments. This realization *approximates* (but is not, and should not be taken to be) the more rigorously defined NAD 83( CORS 96) realization in which Continuously Operating Reference Stations (CORS) are distributed. NAD 83(NSRS2007) was created by adjusting GPS data collected during various campaigns. The adjustment was performed between the mid-1980's and 2005. For this adjustment, NAD 83( CORS 96) positional coordinates were held fixed (predominantly at the 2002.0 epoch for the stable north American plate, but 2007.0 in Alaska) to obtain consistent positional coordinates for the ~70,000 passive marks, as described by Vorhauer [2007]. **Derived NAD 83(NSRS2007) positional coordinates should be consistent with corresponding NAD 83 (CORS 96) positional coordinates from the GPS data used in the adjustment and the accuracy of the corrections applied to these data for systematic errors.** In particular, there were no corrections made to the observations for vertical crustal motion when converting CORS survey into the epoch of the adjustment, while the NAD 83 ( CORS 96) coordinates do reflect motion at CORS sites. **For this reason alone, there can never be total equivalency between NAD 83(NSRS2007) and NAD 83(CORS 96).**
- Note: NGS has not computed (NSRS2007) velocities for any of the ~70,000 passive marks involved in this adjustment. Also, the positional coordinates listed for all marks will make reference to an epoch date. Epoch dates are the date for which the positional coordinates were adjusted and are considered valid (within the tolerance of not applying vertical crustal motion). Because a mark's positional coordinates were adjusted to a specific epoch date, the coordinate of a mark on epochs different than the listed epoch date can only be accurately determined if a 3-dimensional velocity has been computed and applied to that mark.

# Georeferencing Error Corrected

Oregon State University  
College of Engineering

# Discussion

- Ideal to handle transformation at the point cloud level not raster level.
- Repeat data helps identify errors but also creates challenges.
- Many tools are limited in terms of what they can do. Difficult to keep up to date (e.g., Proj library).
- What is the uncertainty posed by the transformation?
- Issues compound with large data volumes.

# Geoescon Research Project @ OSU

Oregon State University  
College of Engineering

- Explores the reliability of point cloud coordinate and reference frame transformations
- Develops robust techniques to perform and evaluate these transformations.
- Focuses on change detection applications where “minor” coordinate system and datum issues (e.g., improper datum realization) can lead to substantial error in change detection
- Produce a “Point Cloud Transformation Toolkit (PoCToK)” capable of geodetic grade transformations.
