

ADC offers a High Pressure Cryo-Cooler for preparing protein crystals used for Crystallography experiment (HPC-201).

This device is into the fourth year of commercialization and has been used in Europe, Asia and the US. There have been great improvements made with each generation. The device's fundamental design is based on a process **developed by Cornell University scientists Prof. Sol M. Gruner and Prof. Chae Un Kim**. The technology enables the simultaneous capture of both amplitude and phase information from a single anomalous diffraction (SAD) of a cryocooled protein crystal, thereby providing sufficient data to solve the crystal structure of a protein with a previously unknown structure. Flash-freezing at atmospheric pressure requires the use of cryoprotectants. Finding the right cryoprotectant for each sample type can be a long, trial-and-error process. The High Pressure Cryo-Cooler eliminates the need to use cryoprotectants and produces superior results.
