

VACCINE NOTICE

4/28/2024

Recent investigation by Marc Girardot: *The Needle's Secret* (2024) presents the contention that vaccination in general may have heretofore unrecognized risks due to lack of control of spread of injected formulations throughout the body. His hypothesis is that the injection process cannot avoid almost instant infusion into blood vessels. In an estimated 2 to 5 percent of injections this charging of the blood vessels is seen to produce damage to epithelial cells and often major organs because of the large dose of nanoparticles in the vaccine that invokes immediate reaction by the immune system antibodies that destroy cells targeted by the vaccine.

The problem arises from the possible escape of the vaccine particles from the deltoid muscle region where they are intended to reside and would not be of harm to other regions that are vulnerable to damage. It is believed that the up to tens of Billions of particles in each dose of recent vaccines is far too many for safety if not confined to the initial site of injection.

The thought is that this inadvertent process has been occurring from vaccinations over many decades and would explain vaccine injuries that have been so far unaccounted for.

In itself this does not constitute a condemnation of the theory of vaccines. The author is not anti-vaccines. He suggests use of patches or other techniques instead of injections.

It may be that other factors will modify this concern. Before making conclusions the reader should consult bona fide medical sources.

This note in no way should be considered medical advice but is only educational.

An informative podcast interview of Marc Girardot by John Campbell on YouTube was recently posted.
