

FILEY : The boulder clay / glacial till cliffs at Filey. The soft, unconsolidated deposits are easily eroded by the waves. They are also easily affected by sub-aerial processes; landslides and rotational slips are common as is the gullying caused by rainwash, and mudflows down the gullies. The beach here is partly composed of the boulders released from the deposit as it is eroded. The great variety of rock types are partly rounded by the attrition process caused by the waves.
