## Another Kind of Invasive Species

There are invasive species that take over our earthy areas as well as our watery ones! One that I see showing up more and more is called **Hoary Alyssum**.

The following description is from the U of M Extension Horse Program:

Scientific Name: *Berteroa Incana*

Hoary Alyssum reproduces by seed and spreads rapidly due to the high number of seed per plant.

Identification:

Stems are grayish-green, hairy and 1 to 3 feet tall with many branches near the top.

Leaves are oblong, grayish-green and covered with rough hairs.

Flowers are white.

This weed is toxic to horses when the fresh plant is eaten in pasture or the dried plant is eaten in hay.

Control: For small infestations, if the weed is flowering, mowing or hand pulling is recommended prior to seed production.

Add some 'bending and pulling' to your exercise program when you are out walking this summer!
