To titer or to revaccinate

Measuring antibody titers is becoming commo remains confusing, even controversial

By Katie Burns

Posted June 15, 2016

When and why has it become more common for veterinarians to measure antibody titers where the cats and dogs?

An antibody titer is a measure of the concentration of antibodies in the blood, as determined diluting a blood sample and exposing those dilutions to an antigen. The shorthand is to refe concentration as titers.

Dr. Richard Ford, emeritus professor of internal medicine at the North Carolina State University College of Veterinary Medicine, said factors inside and outside the profession are driving the increase in antibody titer testing.

In the late 1990s and early 2000s, the American Association of Feline Practitioners, AVMA, and American Animal Hospital Association released guidelines on vaccination suggesting that core vaccines have a longer duration of immunity than one year. The AAFP and AAHA guidelines recommended vaccinating every three years. Dr. Ford said many practices began measuring titers "to provide evidence to themselves that in fact the vaccinations are lasting longer than one year."

Part of the impetus for the guidelines was concerns about the potential adverse effects of vaccines. Recently, Dr. Ford said, concerns about adverse effects of vaccines in children have spilled over into veterinary medicine.

The technology for measuring antibodies also has improved, he said. There are now affordat useful information within 20 to 25 minutes. Dr. Ford said, "Two things loom, and I think every One, what is the indication for using the test? And, two, how do you interpret the test results

For all forms of antibody testing, it remains confusing and even controversial whether the re immunity.

According to the AAHA guidelines, antibody testing is useful for monitoring immunity to certa guidelines recommend defined revaccination intervals for cats. Guidelines from the World S favor antibody testing for determining duration of immunity of core vaccines in dogs. But the Principles" sound a cautionary note.

Principles of titers

According to the AVMA principles: "When serological titers are used to help determine the v animal, veterinarians should make sure these data have been clinically correlated to host-an specific diseases and species being tested. For most common vaccine antigens, the correlation vaccination, long-term serostatus, and protection in the host animal has not been adequated often precludes practitioner's ability to make well-informed vaccination decisions based on s

Dr. Laurel Gershwin, a professor who teaches immunology at the University of California-Da represents immunology on the AVMA Council on Biologic and Therapeutic Agents, which ha Principles." The principles don't make recommendations on specific vaccines or specific vac said there are good data that immunity from core vaccines in cats and dogs should last for t

"For those clients that are reticent about not having a distemper vaccine every single year, f indication to go ahead and do a titer," she said. "Having said that, when we measure antiboo equation."

A cat or dog could respond to a vaccine with a strong cell-mediated immune response, whic research setting. She said, "Even if you have a titer that is less than what is considered acc mean that the pet would get sick if he or she were challenged with just the street virus, walk with a dog that was infected, for example. But, obviously, one would want to boost those."

Dr. Gershwin said the gold standard in titer testing involves sending a blood sample to a lab neutralization assay to measure antibodies to canine distemper virus or parvovirus or to per test to measure antibodies to parvovirus.

Titer testing is a good idea for some cats and dogs, Dr. Gershwin believes. These include a genetic predisposition to poor responsiveness to a vaccine, that have an allergic reaction to vaccine, or that have immunosuppression.

Titers in practice

The AAHA Canine Vaccination Guidelines state that "despite the confusion and controversy testing is useful for monitoring immunity to canine distemper virus, canine parvovirus type 2 rabies virus. The guidelines note, "Some clients are now having titers performed for CDV ar

66 I get the impression that some veterinarians are just not doing any vaccinations until the titer falls into the negative threshold level, and then they boost. So that might mean some dogs or cats will go on for multiple years Dr. Ford of North Carolina State U AAFP guidelines on vaccination, s correspond well to gold-standard t distemper virus, canine parvovirus the parvovirus that causes feline p

The test kits have a variety of app could do titers during animal intak control disease without euthanasia vaccination series for a puppy, the immunized before starting puppy s without needing a vaccination. Some develop excellent levels of antibody that are sustained virtually for their lives following the initial vaccination series. And others don't seem to sustain them that well."

More clients are asking whether b Ford said, and the cost has come the impression that some veterina vaccinations until the titer falls into then they boost. So that might me multiple years without needing a v levels of antibody that are sustain initial vaccination series. And othe well."

Dr. Ford uses the acronym PIE to Depending on the nature of the dis protection, infection, or exposure. Lyme disease or leptospirosis imp titer test for ehrlichiosis implies ex

For titer tests as with all tests, Dr. Ford added, practitioners should consider data on the like negative results.

AAFP recommendations

The AAFP Feline Vaccination Advisory Panel Report states, "Because antibody titers may n the degree of protection or susceptibility for an individual cat, the Advisory Panel recomment intervals rather than measuring antibody titers to assure protection."

According to the report, most cats that have a positive result on a titer test for feline panleukopenia are immune to the disease. Titers for feline herpesvirus-1 and feline calicivirus "may not necessarily correlate well with protective immunity and should not be used to predict protection in the future." Titers for feline leukemia virus and feline immunodeficiency virus "do not correlate with immunity and should not be used to determine the need for vaccination."

Shila Nordone, who holds a doctorate in immunology and was an author on the report, said, "We have yet to determine the role of cell-mediated immunity in protection of the cat long term against specific diseases postimmunization. Antibody titers do correlate with protection but are by no means indicative of absolute protection."

Vaccine formulations vary quite a bit, Dr. Nordone said. The AAFP recommends boostering when protection is likely to begin waning, about halfway through the expected duration of immunity.

Dr. Nordone said vaccines for feline panleukopenia are highly effective, inducing sterilizing immunity, which means the virus is blocked from replicating in the cat. She said, "FCV and FHV vaccines do not induce sterilizing immunity but rather minimize clinical symptoms of disease. Similarly, FIV and FeLV vaccines don't induce sterilizing immunity against the pathogens."

She concluded, "My bias, as an immunologist, is to avoid overimmunization and follow recommendations in order to maintain full protection."

Favoring titers

The Canine Vaccination Guidelines within the WSAVA Guidelines for the Vaccination of Dogs and Cats state that, while antibody testing still can be relatively expensive, "The principles of 'evidence-based veterinary medicine' suggest that testing for antibody status (for either puppies or adult dogs) should be better practice than simply administering a vaccine booster on the basis that this would be 'safe and cost less.'"

Some dogs maintain antibodies for their entire lives to canine distemper, canine parvovirus, and canine adenovirus, said Dr. Ronald D. Schultz, professor of immunology and founding chair of the Department of Pathobiological Sciences Madison School of Veterinary Medicine and an author of the WSAVA and AAHA guidelines.

In his controlled studies, he has found that dogs maintain immunity to CDV, CPV-2, and CA vaccination, as proved by protection against virulent challenge. He said, "The presence of a viruses is a clear indication of protection. There is no confusion on this point."

Dr. Schultz noted that the canine distemper, canine and feline parvovirus, and canine adence live virus vaccines. In general, he said, modified-live virus vaccines provide longer-term imm

"We can use titers to know whether or not the animal does need to be revaccinated, or we or revaccinate," he said. While few practitioners would have thought of doing titers 10 years ag testing today. He said, "Dr. Laurie Larson in my laboratory is running thousands of gold-star is coming from owners who wish to avoid unnecessary booster vaccination."

Dr. Schultz emphasized, "This is something that the owners just need to recognize: how imp puppy and every kitten should receive them. Antibody testing assures us that the dog or cat or not, and is a very useful tool for every small animal practitioner. This is the only practical developed an immune response to a given core vaccine."

Dr. Gershwin of the AVMA Council on Biologic and Therapeutic Agents concluded, "Pet owr veterinarians to determine the best schedule of immunizations for their pet. This will be dep such as allergic reactivity and factors such as being on an immunosuppressive drug."
