Detailed Analysis :

- On detailed analysis following facts were discovered:
 - The digital link between Power Plant Processor to Urea Plant Processor of the existing LMS often suffered from traffic congestions leading to unpredictable delayed actions.
 - Scan time of PLC as a whole often run into seconds not milli seconds.
 - Our GTGs can take a maximum step load of **4MW** and then settle for at least one minute to take further load and so on upto a maximum of around **19MW**.
 - In our Power system “the critical fault clearing time is around 0.32 seconds”(320ms).—In other words the LMS must clear the overloading of GTG ,if any, within 320 ms. maintaining less than 4MW load step and 19MW limit.

Conceptualisation of corrective measures

- It is possible only when all the four Urea Plant loads along with some other non-critical load (total about 13MW) is shed **at a time in less** than 320 ms. by a so-called “**Fast load shedding scheme**” acting as a bypass to existing software algorithm.
- Transfer of trip command from Power Plant Processor to Urea Plant Processor can be done on hardwired connections as an analog contact to avoid data links and delay thereof.

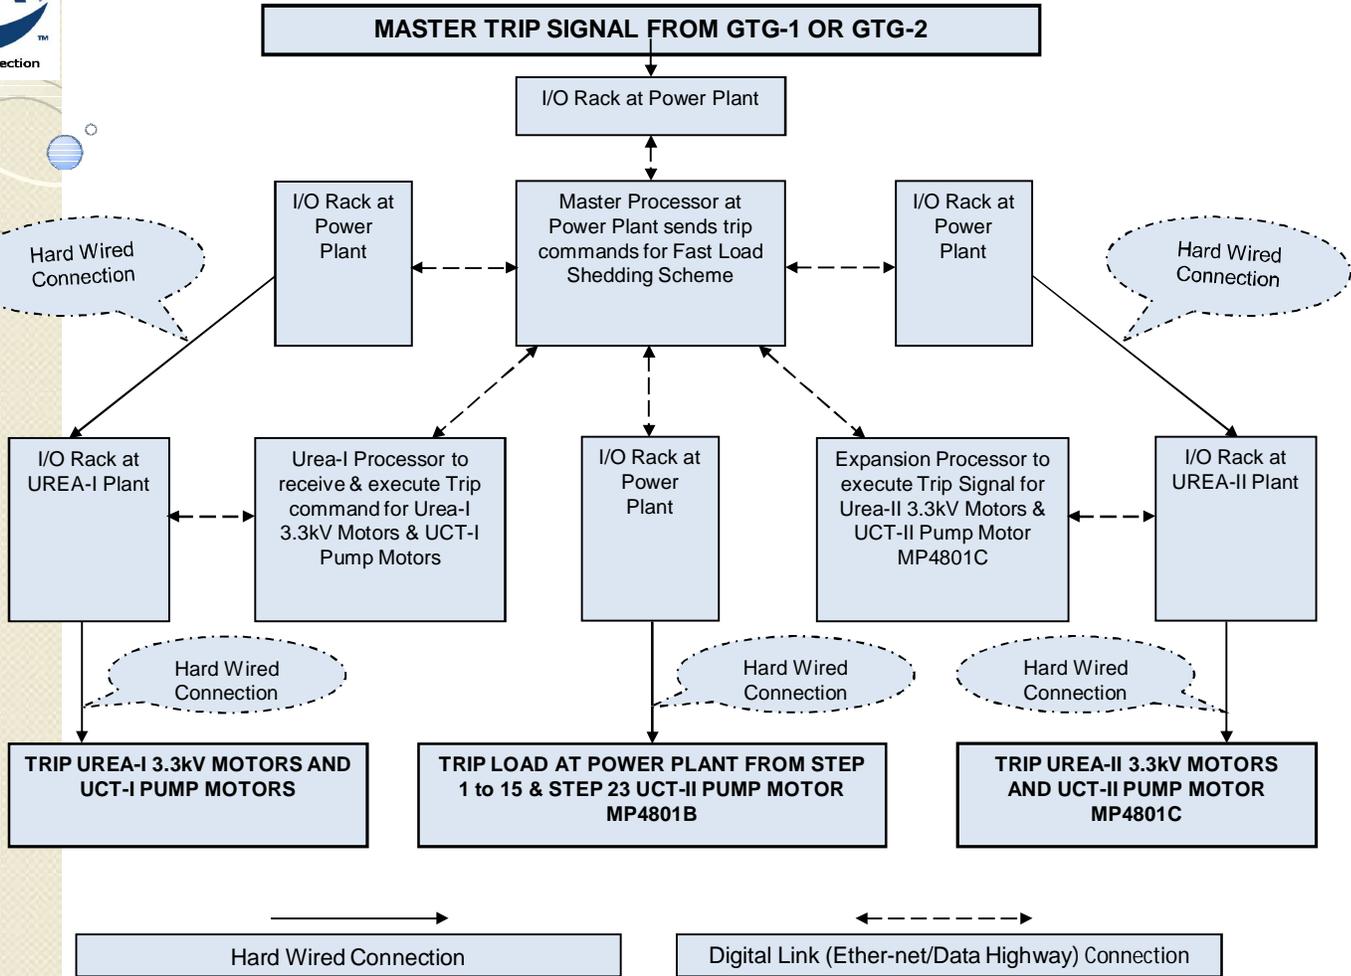

The Fast Path Logic

Note: In case load of a particular step is already 0 (zero) the system automatically proceeds to next step. This is not shown in algorithm.

Note: 5 Sec. initial delay & its bypass not shown

Implementation of Fast Path Logic

Implementation

In the existing PLC, the fast path load shedding implementation scheme was done in line with above concept in steps.

- During this phase the sub-routine was made separately.
- The I/O channel communication rate for power plant and expansion racks for Fast Load Shedding (FLS) I/O was changed from 57.6K to 230.4Kbps for faster execution .
- All the steps as required by fast path scheme were implemented completely.
- The testing was done by way of simulating the fast path load shedding conditions and ensuring actuation of the auxiliary relay upstream of respective circuit breakers.
- The detail of the scan time as measured are also given below.

Implementation-Measured Scan Times

Processor	Scantime before adjustment (ms)	Scantime after adjustment (ms)	Remarks
Power Plant	250	90-120	
Expansion	120	60-70	
Overall(atU2 I/O Rack)		220-250ms	Reqd.320ms

System scan time was found **220-250ms.** as required

Implementation—Other Measures

Other measures were also taken to ensure earlier causes of GT trip does not re-occur, nor the utilities like cooling water or lube oil fails to the critical rotary machines.

Also a list of equipment to be run to survive ammonia plants under power crisis situations were made and scenario of process and equipments under such situation was also worked out. Operating instructions were given accordingly.

Under frequency relay back-up

Other Measures for Reliability enhancement

It was noted that both GTGs have earlier tripped on occasions of earth fault of Township overhead cables and earth faults at Ammonia-I sub station.

- The earth fault relay installed earlier at Township used to act slower than protection relay installed at GTG end and allowed the fault to propagate to GTGs and trip them. For some period the Township load was removed from GTGs and kept on UPPCL.
- New Microprocessor based MICOM relays are now installed for feeder protection of Ammonia Plant, Bore-well and Township Feeders for fast isolation of fault,
